tive endeavors in such a way as to create a political issue in the campaign interests of the members of the board of supervisors and contrary to the dignity and honor of the medical profession. The petitioner filed a denial of the charges, hearings were had before the committee on grievances and the board of directors of which the petitioner had due notice but which he voluntarily did not attend. As a result of the hearings, the petitioner was expelled from the society. Appeals from the expulsion order were taken to the California Medical Association and to the American Medical Association, each of which in turn affirmed the order of expulsion. Following this the petitioner applied unsuccessfully to the superior court of Kern County for a writ of mandamus to compel his reinstatement, and from that adverse judgment he appealed to the district court of appeal, 4th district, California, which reversed the findings of the trial court and, in effect, ordered the petitioner's reinstatement to membership. (*Smith v Kern County Medical Association*, 112 P (2d) 268, J A M A 117 63 [July 5] 1941.) Accordingly the society prosecuted an appeal to the Supreme Court of California.

The trial court found, said the Supreme Court, that the amendments to the constitution and by-laws were regularly and duly adopted and that the petitioner expressed his approval of such amendments and consented to be governed thereby by his signature duly and regularly endorsed thereon, and that he agreed to be bound by the principles of ethics adopted by the society. It also found that the charges against the petitioner constituted a violation of the principles of medical ethics and of the laws of the society, that the proceedings against the petitioner were all duly and regularly taken, that neither the resolution adopted by the society nor the expulsion proceedings were part of any unlawful plan or scheme, and that the petitioner would not be deprived of any property right. There was sufficient evidence in the record, in the opinion of the Supreme Court to support these findings of the trial court. In any proper case involving the expulsion of a member from a voluntary unincorporated association, the only function that the courts may perform is to determine whether the association has acted within its powers in good faith, in accordance with its laws and the law of the land. The procedure provided by the rules of the society was followed and the petitioner was accorded every opportunity to defend himself. He may not be allowed to complain that hearings, of which he had due notice and opportunity to attend, were conducted in his absence when he voluntarily absented himself from the hearings.

The petitioner contended that the termination of proceedings instituted against him in 1932 and 1933 without disciplinary action amounted to an acquittal of the charges and precluded the society from again accusing him. There was no merit in this contention said the Supreme Court. The practices which formed the basis of the charge were continuing and the present accusation was filed on the failure of the petitioner to resign after the adoption of the 1935 resolution. Not only was it the service on the hospital staff which the society ruled to be a breach of ethics but such violation was expressly deemed to be service on the staff while the conditions persisted which were contrary to the rules of ethical practice formulated by the society. The courts may not properly declare, said the Supreme Court that such a society may not expel a member who persists in practices which, by the rules of the society and the written agreement of the member himself, are unethical.

The petitioner argued that the provisions of the by-laws of which violation was charged were part of other provisions relating to contract practice and that since he was not engaged in contract practice as such he should not be expelled for taking an active part in creating the same conditions condemned in relation to contract practice. It was not necessarily the practice by name which was disapproved by the society, held the Supreme Court, but certain express conditions thereby created. The record discloses and the society found that the petitioner had continued an activity which created such conditions. Any matter of policy involved in the adoption of the by-laws, the code of ethics and the resolution in conformity therewith was a question for the membership itself and may not be considered by a court so long as it is not shown that such policy is in violation of law.

The Supreme Court, in conclusion, said that the contractual relation between the society and one of its members is that which exists by virtue of the rules of the society, and so long as the society acts toward him in accordance with those rules there is no violation of the contract. The judgment of the superior court sustaining the petitioner's expulsion was affirmed.—*Smith v Kern County Medical Association*, 120 P (2d) 874 (Calif. 1942).

Workmen's Compensation Acts Refusal to Submit to Operation—While in the employ of the appellant company, the claimant received severe injuries to his pubic bone. Roentgenograms were taken on three separate occasions by three different physicians, and the claimant, on the advice of a fourth physician, wore a brace for several months. At the end of that time he was advised that the brace had failed in its purpose, and it was suggested that he submit to an operation in an endeavor to fuse the broken and displaced pieces of bone. The physician who recommended this operation would not guarantee the results. The claimant then consulted the physician who had taken the first roentgenograms and was advised by him that an operation would not improve his condition. The same advice was given to him by another physician of his own selection. He therefore refused to submit to the operation. Subsequently an award was granted the claimant under the workmen's compensation act, the award was affirmed by the circuit court and the company appealed to the Court of Appeals of Kentucky.

The company denied liability because of the claimant's refusal to submit to the operation. Counsel for both parties agreed that when there is no contrariness of evidence on the question compensation will be denied if the claimant is able but refuses to submit to an operation when the latter is not unusually hazardous and will practically eliminate the disability. In this case, although several physicians testified that the operation was not unduly hazardous and that in their opinion a complete cure would be effected, they all admitted that the operation was a major one. On the other hand, a physician selected by the claimant and the physician to whom the claimant was first referred by the employer were of the opinion that an operation would not be beneficial and that more serious injuries might result. The claimant, the court said, was not required to follow the advice of one physician in preference to another, especially when the physician whose advice it is insisted should be followed is a physician selected by the party opposing the claimant's claim. A patient must be accorded a certain discretion in the selection of the physician whose advice he desires to follow, and the courts will not make that selection for him unless he refuses to make it for himself or unless it is shown that the physician selected is not skilled in his profession. Courts will not force a claimant to risk his life in order that the company legally bound to compensate him may be given an opportunity to reduce its liability. A claimant has the right to remain in a helpless condition so far as earning a livelihood is concerned, in preference to taking a chance on additional disability which might result in an endeavor to cure his present condition.

In the opinion of the court the evidence was sufficient to support the findings and award of the industrial commission and therefore the judgment of the lower court in favor of the claimant was affirmed.—*Kentucky Jellico Coal Co v Lee*, 158 S W (2d) 385 (Ky., 1942).

Intestinal Parasite Infections.—The intestinal parasite incidence was determined by the microscopic examination of stool specimens and/or scrapings from the perianal region of 319 charity patients of three hospital units of the Indiana University Medical Center. The incidence as reported by Headlee was 18, or 7 per cent of 285 persons for one or more species of worms whose stools were examined, 13, or 5 per cent were infected with the pinworm. The perianal scrapings of 319 individuals revealed that 27 or 8.5 per cent were infected with helminths of one or more species, 22 were infected with pinworms. Comparison of the data with the results of other surveys in Indiana and states to the south shows that the incidence of *Endameba histolytica*, 0.8 per cent, is considerably lower than the estimated 5 to 10 per cent for the general population of the

United States. The incidence of infection with *Endameba coli*, *Endameba nana*, *Giardia lamblia*, *Endameba buetschli*, *Chilomastix mesnili* and *Trichomonas hominis* is slightly higher for Indiana than for some of the states to the south. The helminth infections appear to be light and scattered throughout the area, if *Enterobius* is not considered. The one hookworm infection found was the first native case encountered by the author in Indiana. The incidence of *Hymenolepis nana* was 0.4 per cent, the same as that reported for Mississippi in 1934 and 1936. The incidence of 0.8 per cent for *Ascaris* and *Trichuris* does not compare with the higher incidence found in Kentucky and Tennessee. In no case was the stated primary cause of hospitalization a gastrointestinal disturbance. The 2 persons infected with *Endameba histolytica* had diarrheic or mushy diarrheic stools but this was not their major complaint and the possibility of an amoebic infection was not mentioned in the diagnosis. The 319 patients, aged from 6 weeks to 78 years examined were from seventy five of the ninety two counties of Indiana.

Low Carbohydrate Diet Therapy of Tuberculosis.—Sandler and Berke selected 10 patients for a trial of a low carbohydrate diet in pulmonary tuberculosis. The patients were not fit for any form of collapse therapy and their prognosis was poor. The diet ranged from 2,309 to 2,920 calories and consisted of 114 to 124 Gm of carbohydrate, 101 to 129 Gm of protein and 161 to 212 Gm of fat. Excepting six soda crackers allowed daily, the carbohydrate content of the diet was ingested in the form of 5 and 10 per cent vegetables and fruits and dairy products. Bread, cereals, potatoes, sugar, corn, rice, tapioca, split peas, noodles, macaroni, spaghetti, cake, candy, ice cream, pancakes and the like were completely avoided. Soy bean flour muffins were given from time to time and enjoyed. Patients were encouraged to eat nuts between meals if they were hungry but high carbohydrate nuts, such as peanuts and cashews were not allowed. After going on the diet they usually complained of being hungry after meals. After a week or two this hunger disappeared and the desire for carbohydrate rich foods usually subsided. All the patients responded favorably, and improvement was progressive and permanent as long as they continued on the diet. Prompt exacerbation of symptoms was reported by 1 patient when he left the hospital and, because he was unable to purchase the more expensive proteins and fats went back to a high carbohydrate diet. Digestive symptoms returned promptly in another patient who ate small quantities of carbohydrate rich foods when he went to the Country Sanatorium. Seven of the patients gained from 5 to 25 pounds (2.2 to 11.2 Kg) after an initial loss of 4 pounds (1.8 Kg) during the first three weeks in 1, 1 patient lost 5 pounds without regaining any in 1 there was no change and 1 who lost 10 pounds (4.5 Kg) subsequently regained this weight. Common digestive complaints, such as fullness after meals, belching, heartburn, flatulence, epigastric heaviness and abdominal cramps, disappeared after a few days. The fact that similar symptoms in patients without tuberculosis or other infections respond to the change in diet is further evidence that they are not due directly to the infection. Relief from precordial symptoms (pain heavy-

tive endeavors in such a way as to create a political issue in the campaign interests of the members of the board of supervisors and contrary to the dignity and honor of the medical profession. The petitioner filed a denial of the charges, hearings were had before the committee on grievances and the board of directors of which the petitioner had due notice but which he voluntarily did not attend. As a result of the hearings, the petitioner was expelled from the society. Appeals from the expulsion order were taken to the California Medical Association and to the American Medical Association each of which in turn affirmed the order of expulsion. Following this the petitioner applied unsuccessfully to the superior court of Kern County for a writ of mandamus to compel his reinstatement, and from that adverse judgment he appealed to the district court of appeal, 4th district, California, which reversed the findings of the trial court and, in effect, ordered the petitioner's reinstatement to membership. (*Smith v Kern County Medical Association*, 112 P (2d) 268, J A M A 117 63 [July 5] 1941) Accordingly the society prosecuted an appeal to the Supreme Court of California.

The trial court found, said the Supreme Court, that the amendments to the constitution and by-laws were regularly and duly adopted and that the petitioner expressed his approval of such amendments and consented to be governed thereby by his signature duly and regularly endorsed thereon, and that he agreed to be bound by the principles of ethics adopted by the society. It also found that the charges against the petitioner constituted a violation of the principles of medical ethics and of the laws of the society, that the proceedings against the petitioner were all duly and regularly taken, that neither the resolution adopted by the society nor the expulsion proceedings were part of any unlawful plan or scheme, and that the petitioner would not be deprived of any property right. There was sufficient evidence in the record, in the opinion of the Supreme Court, to support these findings of the trial court. In any proper case involving the expulsion of a member from a voluntary unincorporated association the only function that the courts may perform is to determine whether the association has acted within its powers in good faith, in accordance with its laws and the law of the land. The procedure provided by the rules of the society was followed and the petitioner was accorded every opportunity to defend himself. He may not be allowed to complain that hearings, of which he had due notice and opportunity to attend, were conducted in his absence when he voluntarily absented himself from the hearings.

The petitioner contended that the termination of proceedings instituted against him in 1932 and 1933 without disciplinary action amounted to an acquittal of the charges and precluded the society from again accusing him. There was no merit in this contention, said the Supreme Court. The practices which formed the basis of the charge were continuing, and the present accusation was filed on the failure of the petitioner to resign after the adoption of the 1935 resolution. Not only was it the service on the hospital staff which the society ruled to be a breach of ethics but such violation was expressly deemed to be service on the staff while the conditions persisted which were contrary to the rules of ethical practice formulated by the society. The courts may not properly declare, said the Supreme Court, that such a society may not expel a member who persists in practices which, by the rules of the society and the written agreement of the member himself, are unethical.

The petitioner argued that the provisions of the by-laws of which violation was charged were part of other provisions relating to contract practice and that since he was not engaged in contract practice as such he should not be expelled for taking an active part in creating the same conditions condemned in relation to contract practice. It was not necessarily the practice by name which was disapproved by the society, held the Supreme Court, but certain express conditions thereby created. The record discloses and the society found that the petitioner had continued an activity which created such conditions. Any matter of policy involved in the adoption of the by-laws, the code of ethics and the resolution in conformity therewith was a question for the membership itself and may not be considered by a court so long as it is not shown that such policy is in violation of law.

The Supreme Court, in conclusion, said that the contractual relation between the society and one of its members is that which exists by virtue of the rules of the society, and so long as the society acts toward him in accordance with those rules there is no violation of the contract. The judgment of the superior court sustaining the petitioner's expulsion was affirmed.—*Smith v Kern County Medical Association*, 120 P (2d) 874 (Calif., 1942)

Workmen's Compensation Acts Refusal to Submit to Operation—While in the employ of the appellant company, the claimant received severe injuries to his pubic bone. Roentgenograms were taken on three separate occasions by three different physicians, and the claimant, on the advice of a fourth physician, wore a brace for several months. At the end of that time he was advised that the brace had failed in its purpose, and it was suggested that he submit to an operation in an endeavor to fuse the broken and displaced pieces of bone. The physician who recommended this operation would not guarantee the results. The claimant then consulted the physician who had taken the first roentgenograms and was advised by him that an operation would not improve his condition. The same advice was given to him by another physician of his own selection. He therefore refused to submit to the operation. Subsequently an award was granted the claimant under the workmen's compensation act, the award was affirmed by the circuit court and the company appealed to the Court of Appeals of Kentucky.

The company denied liability because of the claimant's refusal to submit to the operation. Counsel for both parties agreed that when there is no contrariness of evidence on the question compensation will be denied if the claimant is able but refuses to submit to an operation when the latter is not unusually hazardous and will practically eliminate the disability. In this case, although several physicians testified that the operation was not unduly hazardous and that in their opinion a complete cure would be effected, they all admitted that the operation was a major one. On the other hand, a physician selected by the claimant and the physician to whom the claimant was first referred by the employer were of the opinion that an operation would not be beneficial and that more serious injuries might result. The claimant the court said, was not required to follow the advice of one physician in preference to another, especially when the physician whose advice it is insisted should be followed is a physician selected by the party opposing the claimant's claim. A patient must be accorded a certain discretion in the selection of the physician whose advice he desires to follow, and the courts will not make that selection for him unless he refuses to make it for himself or unless it is shown that the physician selected is not skilled in his profession. Courts will not force a claimant to risk his life in order that the company legally bound to compensate him may be given an opportunity to reduce its liability. A claimant has the right to remain in a helpless condition, so far as earning a livelihood is concerned in preference to taking a chance on additional disability which might result in an endeavor to cure his present condition.

In the opinion of the court the evidence was sufficient to support the findings and award of the industrial commission and therefore the judgment of the lower court in favor of the claimant was affirmed.—*Kentucky Jellico Coal Co v Lee*, 138 S W (2d) 387 (Ky 1942)

Low Carbohydrate Diet Therapy of Tuberculosis.—Sandler and Berke selected 10 patients for a trial of a low carbohydrate diet in pulmonary tuberculosis. The patients were not fit for any form of collapse therapy and their prognosis was poor. The diet ranged from 2,309 to 2,920 calories and consisted of 114 to 124 Gm of carbohydrate, 101 to 129 Gm of protein and 161 to 212 Gm of fat. Excepting six soda crackers allowed daily, the carbohydrate content of the diet was ingested in the form of 5 and 10 per cent vegetables and fruits and dairy products. Bread, cereals, potatoes, sugar corn, rice, tapioca, split peas, noodles, macaroni, spaghetti, cake, candy, ice cream, pancakes and the like were completely avoided. Soy bean flour muffins were given from time to time and enjoyed. Patients were encouraged to eat nuts between meals if they were hungry but high carbohydrate nuts, such as peanuts and cashews were not allowed. After going on the diet they usually complained of being hungry after meals. After a week or two this hunger disappeared and the desire for carbohydrate rich foods usually subsided. All the patients responded favorably, and improvement was progressive and permanent as long as they continued on the diet. Prompt exacerbation of symptoms was reported by 1 patient when he left the hospital and because he was unable to purchase the more expensive proteins and fats went back to a high carbohydrate diet. Digestive symptoms returned promptly in another patient who ate small quantities of carbohydrate rich foods when he went to the Country Sanatorium. Seven of the patients gained from 5 to 25 pounds (2.2 to 11.2 Kg) after an initial loss of 4 pounds (1.8 Kg) during the first three weeks in 1, 1 patient lost 5 pounds without regaining any, in 1 there was no change and 1 who lost 10 pounds (4.5 Kg) subsequently regained this weight. Common digestive complaints, such as fullness after meals, belching, heartburn, flatulence, epigastric heaviness and abdominal cramps, disappeared after a few days. The fact that similar symptoms in patients without tuberculosis or other infections respond to the change in diet is further evidence that they are not due directly to the infection. Relief from precordial symptoms (pain, heavy-

ness over the chest, palpitation and dyspnea) at rest and on exertion also occurred. Cough wheezing and difficulty in raising sputum were either completely relieved or greatly ameliorated. There was a striking improvement in the mental state of the patients, they appeared more buoyant and hopeful. Five patients have returned to their homes, it was possible to prepare 2 for surgery and 3 are still in the hospital and improving steadily. The beneficial effects on the diet are attributed to increased dextrose oxygen consumption brought about by elevating the blood sugar to normal levels in patients with hypoglycemia, by restricting carbohydrate rich foods in patients with hyperglycemia and by making available the more highly reactive γ -dextrose in patients with neither hypoglycemia nor hyperglycemia. A low carbohydrate, high protein diet probably brings about a normal liver glycogen storage which is necessary for adequate delivery of endogenous dextrose to tissues so that cellular oxidations may be maintained at an optimal level.

Treatment of Experimental Tuberculosis—Barach and his associates repeated the experiments of Feldman, Hinshaw and Moses, who reported that the sodium salt of *p,p'*-diaminodiphenylsulfone-*N,N'*-dixetrose sulfonate had an inhibitory effect on the development of experimental tuberculous infection in guinea pigs. Slight variations in the procedure showed that the oral route did not offer as great a concentration of the drug in the lungs and a lower concentration in the blood as did local application of the nebulized spray of the compound. The inhalation of the nebulized spray had a deterrent influence on the development of generalized tuberculosis in 22 of 28 guinea pigs as compared to 10 infected, untreated control animals. Despite a lower concentration of the compound in the blood of animals who had inhaled the nebulized spray, the degree of pulmonary and generalized tuberculosis was less than in the orally fed group. Of 16 animals treated by inhalation, 13 survived for the eighty four days of the experiment whereas the 14 animals given the compound by mouth and the 17 untreated animals did not survive beyond the seventy-fifth day. Inhalation of the nebulized spray has been carried out on 3 patients with advanced pulmonary tuberculosis.

The Chemotherapy of Tuberculosis—Zucker and his co workers administered the sodium salt of *p,p'*-diaminodiphenylsulfone-*N,N'*-dixetrose sulfonate to 12 tuberculous patients by the continuous intravenous drip method. The toxic effects, fever up to 101 F and slight anorexia, cyanosis, weakness, headache and drop in hemoglobin were usually slight and transient. Of 2 patients who received 25 Gm per kilogram of body weight of the compound daily blood levels were maintained between 10 and 154 mg per hundred cubic centimeters and in them the common toxic symptoms of sulfamidamide ensued but, when the daily dose was reduced to 15 Gm, disappeared promptly. The patients were observed for four to seven months after one to two months of treatment with the compound was begun. Three patients died respectively eight, five and two weeks after receiving it. All the patients had been on bed rest for one month to two years before the therapy was begun. Objective evidence indicated that on bed rest there was progression in 8, no change in 1 and slight improvement in 3. Bed rest was continued in each while the compound was administered. It did not alter the expected course of the disease in any of the patients, with the possible exception of 1 with an extensive ulcerocaseous tuberculosis of the right main bronchus and the lower part of the trachea. The ulcerations became less extensive and more fibrotic, and bronchoscopists were of the opinion that the rate of healing was faster than could be anticipated. The improvement of 2 patients was no better than is often found for such lesions on bed rest alone. The progression in 4 patients was particularly significant since their lesions were early and non-destructive. In 1 not only did the new pulmonary infiltrations progress and excavate during and after treatment, but symptoms and roentgen signs of intestinal tuberculosis appeared. It is the authors' contention that the drug as given is ineffective against clinical tuberculosis. Their clinical observations are at variance with the successful results in tuberculous guinea pigs. The discrepancy should serve to emphasize again the difficulty of translating laboratory into clinical experience. The action

of drugs may not be the same in the guinea pig and in man. The clinical results are disappointing, but they make it necessary more than ever to extend the search for a drug that will cure tuberculosis.

Vascular Accidents in Migraine—A case of migraine is reported by Dunning in which a cerebral hemorrhage occurred during an attack. The relevant literature revealed 6 similar cases. Five of the patients were women, all were 18 to 37 years of age at the time of the first accident. There were ten vascular hemorrhages and one retinal infarction; only one caused death. Of the ten hemorrhages, seven involved the eye and were directly observed. The other three were cerebral, two were detected by the presence of blood in the spinal fluid and one was observed directly at necropsy. Three cerebral hemorrhages occurred during menstruation; five (three ocular and two cerebral) occurred at the time of headache and were precipitated by activity producing sudden increase in pressure within the blood vessels of the head. Two other ocular hemorrhages were discovered soon after such activity during the headache. The author concludes that, unless such vascular accidents can be attributed to latent structural lesions of the cranial blood vessels, migraine should be regarded as a disordered function capable of causing irreversible tissue change.

Brain Abscess—Odom and Elvidge present the clinical history of a patient who four months after an attack of typhoid was operated on for an expanding intracranial lesion which proved to be a cerebral abscess from which a pure culture of *Eberthella typhosa* was obtained. On discharge on the twentieth postoperative day neurologic examination revealed nothing abnormal. This is probably the first case of cerebral abscess proved to be due to *E. typhosa* following typhoid which was discovered before death and the first in which neurosurgical treatment was effective.

- Progress in Orthopedic Surgery for 1941. Review Prepared by Editorial Board of the American Academy of Orthopedic Surgeons—p 443

Intracranial Arterial Aneurysms in Carotid Canal—In a review of 108 arterial aneurysms of the brain that came to operation or necropsy Dandy states that 9 were in the carotid canal, in 1 the condition was bilateral. He has collected 27 additional cases from the literature, in 3 of which the condition

was bilateral. According to signs and symptoms, aneurysms of the carotid aneurysm of three types: (1) those giving palsies of the extraocular muscles, (2) those giving trigeminal neuralgia and corresponding sensory loss and (3) a combination of the two types. The most important manifestations of an aneurysm in this region are palsy or paralysis of the third nerve and periodic severe pain in the affected eye or frontal region. These disturbances are equally present with intracranial aneurysms of the internal carotid or even of the posterior communicating artery. When to this pain and paralysis is added involvement of the first and second branches of the trigeminal nerve (eventually of all three branches) the diagnosis of an aneurysm in the carotid canal is almost absolute. Usually paralysis of the fourth and sixth nerves coexists. Loss of vision is an important and common subjective and objective disturbance. At times papilledema results from intracranial pressure as the aneurysm grows upward into the cranial chamber. The fact that aneurysms are due to defective arterial walls predisposes them to rupture. Exophthalmos occurs only with large aneurysms which have eroded the walls of the sphenoid fissure. The ages of patients at operation death or disclosure of the aneurysm are fairly evenly distributed in all decades. The duration of symptoms varies considerably, from a few weeks or months to twenty-five years. The fact that the aneurysms in 13 were actually disclosed at operation testifies to the recent great progress in neurosurgery. Angiography is inadvisable, as it is not without risk. In 1 case it did not disclose the lesion subsequently found at operation. Patients are better off without it. Of 7 patients operated on 1 died, this patient being operated on for a carotid cavernous arteriovenous aneurysm and at necropsy the cause of the arteriovenous aneurysm was found to be rupture of two small arterial aneurysms in the carotid canal. Death was due to rupture of an oversize arteriosclerotic artery during the application of a silver clip that was too small. This was the only accident in more than 20 closures of the carotid intracranially. The other 6 patients were cured the longest for three and a half years.

Acute Surgical Parotiditis—Among 95,355 admissions to St. Mary's Hospital and to the Grinnell Desloge Hospital parotiditis had developed, according to Coughlin and Gish in 44. The cases occurred among the medical and surgical services. Most of the patients were females. In 17 it followed abdominal operations, eight of which were for gynecologic conditions (1 in every 400 gynecologic operations). Parotiditis occurred most often in those with dry and at the same time poorly cleansed mouths (tongue and teeth). The most frequent bacterial cause was *Staphylococcus aureus* and *albus*. Early chemotherapy is indicated, sulfathiazole is probably best. The mortality is lower among those in whom there are early surgical indications for incision and uncovering of the gland. Simple incision is only for a frank abscess. Radiation appears to be a valuable form of treatment. The safe operative treatment consists in uncovering the whole gland and making multiple openings in its substance with a blunt instrument.

Influence of Dietary Fat on Excretion of Urobilin—The finding of an increased urobilin output in the stools of normal infants on high fat diets raised questions as to the interpretation of this phenomenon. Of the various possible

explanations Josephs and his collaborators believe that the most satisfactory is that absorption of increased amounts of soap on a high fat diet or a diet to which free fatty acid or soap have been added leads to increased hemolysis. The effect on urobilin is independent of the type of fat fed. A high fat diet causes a sudden but temporary increase in the output of iron in the feces.

March Fracture—Sirbu and Palmer suggest that march fracture is a stress fracture secondary to a developmental anomaly. It occurs in young soldiers unused to long marches, but only in those whose feet are inherently weak or flat and mechanically unsuited to withstand the exertion. The authors treated 15 such cases in eighteen months. They constituted 25 per cent of all fractures of the metatarsals seen during the same period. The previous occupation of the group was either sedentary or of a physical type requiring no exhaustive hiking or rhythmic marching. Regarding some contributing injury, 11 volunteered no specific incident of trauma and 4 claimed comparatively minor accidents, stubbing or bumping of the foot, which were insufficient to warrant immediate medical attention. This tends to substantiate the claim that march fracture is caused by rhythmic movements, multiple mechanical insults or microtraumatism. Furthermore, continued prolonged weight bearing could cause dissemination of the fracture hematoma and excessive callus formation. The metatarsal involved was the second in 7 and the third in 8. This predilection for the second and third metatarsals also tends to substantiate the predisposing cause for the condition. Roentgen studies in all revealed a relatively short first metatarsal compared to the second. The sesamoids which bear the initial brunt of the takeoff, were proximally located and the shortening effect was further increased. The weight, which should be borne by the heavier and stronger first metatarsal was shifted to the two adjacent metatarsals, which were long and slender and ill equipped to bear the person's weight and a heavy pack. The base of the second and third metatarsals was relatively fixed so that as the full load was placed on its head considerable stress was transmitted to the shaft which cracked at its weakest point. From a developmental standpoint, in those individuals in whom the first metatarsal fails to reach at least a comparatively equal length to the second a potentially weak foot results, the so-called atavistic foot. March foot may be considered as an end result of subacute flatfoot occurring in a congenitally weakened foot. This developmental anomaly was noticed not only in the 15 men but also in all similar reports in the literature with satisfactory roentgen studies. A metatarsal pad strapping to relieve the weight from the head of the afflicted bone and an anterior heel or metatarsal bar to the shoe were usually sufficient. Local heat, light massage and exercises were beneficial. The average length of disability was twenty-one days. There were no after effects or recurrences.

Etiology of Impetigo Contagiosa—The conviction that in impetigo contagiosa some agent other than staphylococci or streptococci was operative led Campbell to suppose that an infectious rather than a contagious process was the etiologic agent.

If a filtrable virus is premised as being the etiologic agent, many phenomena are possible of acceptance. The minor clinical variations could be explained as being due to the symbiotic action of a secondary organism dominant in the lesion. Assuming the theory to be correct, any primary pure culture of staphylococci or streptococci would be so intimately associated with the virus that it would be present in sufficient strength to reproduce the disease. Pinpoint subcultures would not carry the virus over in reproductive strength. Lesions have been produced using primary cultures of staphylococci but not with subcultures. The fact that on several occasions the author was unable to reproduce the disease with material taken direct from freshly denuded previously untreated lesions persuaded him that regional as well as soil factors play no small part in the reproduction of the disease and that other factors obtain. Certainly it is not as contagious as one has been led to believe and although the frequent involvement of the face suggests a regional sensitivity, daily practice suggests a covered area to be the region of choice for inoculation. The author's experiments on himself with Berkefeld filtrates of washings or swabbings taken from active untreated lesions of the disease produced several scattered itching points which in six days were pronounced as impetigo contagiosa by Saul Robinson.

Pulmonary Fat Embolism—Wile and Schamberg attempted to determine the feasibility of using the bone marrow route for massive arsenotherapy of syphilis. Rabbits were given by bone marrow infusion drip daily for five days 4 mg of mapharsen per kilogram of body weight. Massive intravenous arsenotherapy was administered to 2 control rabbits. Pulmonary fat emboli were demonstrated in 5 of the 7 rabbits treated via the bone marrow. No fat emboli were seen in the 2 animals treated by vein. In view of this finding the authors do not believe that the procedure can at present be considered free from hazard in human beings.

Renal Hypertension and Nephrectomy—During 1940 and 1941 528 patients with hypertension had pyelograms made by Ratliff and Conger to determine whether the kidneys were affected or not. Of these 340 had urinary symptoms (nocturia) and 188 did not. In the symptomatic group there were many patients who had gross hematuria and gross infection. Thirty-two of the 340 patients had renal disease. 15 were considered to have congenital abnormalities which had nothing to do with the increased blood pressure, they represented the type of case in which operation would not relieve the hypertension. The remaining 17 had renal conditions compatible with hypertension. 12 had chronic pyelonephritis and 5 renal calculi. Only 2 of the 12 with chronic pyelonephritis might have been improved by nephrectomy, as in 7 the involvement was bilateral and in the 3 with so called unilateral involvement the diagnosis was questionable. There remain 7 of 340 who might possibly be treated and benefited by operation. The pyelograms of 285 were negative and of 23 inconclusive. Of those with urinary symptoms 110 had negative, 30 inconclusive and 48 positive pyelograms. During 1935 and 1936, 211 patients had a nephrectomy performed, 73 had a preoperative elevation of blood pressure higher

dian a systolic of 140 and a diastolic of 90. Only 32 of the 73 were adequately followed for purposes of study and in none of them did the pressure exceed 200/110, that is, they may be classified as having relatively benign hypertension. The diseases of the 32 were pyelonephrosis, tuberculosis, calculus disease, neoplasm and pyelonephritis. The pressure of 11 of the 32 returned to normal or was definitely improved, that of 8 showed no postoperative change, the blood pressure readings of 8 were progressively higher and 5 died during the period of study. One of the deaths was directly attributed to hypertension. Six of the 9 nephrectomized hypertensive individuals cared for during 1940 and 1941 and adequately enough followed for two to ten months had a blood pressure above 200 systolic and 100 diastolic, that is, they had preoperative or malignant pressures. In 3 there was a postoperative regression of blood pressure to normal, that of 3 was improved and in 3 there was no definite change. As stabilization means improvement, the 9 may be considered 100 per cent improved, with a possible cure in 33⅓ per cent. Until a more selective test has been adopted, any patient with hypertension in whom unilateral renal disease can be demonstrated should be subjected to a nephrectomy, not only as a cure for the local lesion, but also with the hope that the hypertension will be relieved.

Primary Lymphosarcoma of Bladder—Kreutzmann states that a careful checking of the literature, not only for sarcoma, but also for the various types of this growth involving the bladder, reveals many duplications, so that only 2 cases of authentic lymphosarcoma have been reported up to 1910 and only 2 additional cases since then. He presents the fifth authentic case of primary lymphosarcoma of the bladder. The tumor originates from the lymphoid tissue in a chronically irritated bladder. It is a localized condition with no evidence of generalized glandular enlargement. Early diagnosis and radical excision will give the most favorable results.

Carcinoma of Prostate—Of 316 patients coming to operation for various types of urinary obstruction, Hannu found carcinoma in 41 and operated on 38. Their average age was 66.4 years, the oldest was 79 and the youngest 45. In 31 the diagnosis of cancer was confirmed by microscopic study, in 1 carcinoma was considered to be possible, in 4 microscopic study did not support the diagnosis but it was established as carcinoma clinically, and from 2 tissue was not obtained. Eighteen had roentgen evidence of metastasis at the time of operation. In 5 no roentgenograms were taken, but in 2 of these there was definite clinical evidence of metastasis to the bones. The key to early diagnosis lies in semannual rectal examination of all male patients 50 or more years of age. Needle biopsy may be of value in diagnosing the early neoplasm, although a negative result is not conclusive. A more dependable method of diagnosis in questionable cases is to expose the gland through a perineal approach and to remove the suggestive nodule for examination by the frozen section method. Curative treatment consists in radical perineal resection. Palliative therapy (surgery and/or irradiation) is indicated when the neoplasm has so developed that radical surgery is impossible. It prolongs life and relieves discomfort and urinary retention. The good effects of castration in cases of advanced prostatic carcinoma have recently been reported by Huggins. The author performed orchiectomy on 5 of his patients in whom the encouraging results are too recent for evaluation. Of the 38 patients there has been no postoperative follow-up on 6, 9 have been lost track of after three months to three years, 15 are known to be dead, 8 patients are in excellent health and 1 who has survived the longest (five years and eight months) is not well. He has radiating pain to the penis, and orchiectomy has been advised.

Ether in Prolonged Operations—Danna states that, with the use of ether as the anesthetic for long operations, a major operation, including the most serious abdominal surgery, can be continued over an additional period of one hour or more after a patient has been surgically anesthetized for not less than fifteen minutes. The exact time probably depends on individual peculiarity, in 1 instance the operation was continued for two hours and fifteen minutes after an initial twenty minutes of anesthesia. The analgesia produced by ether continues long after the patient is sufficiently conscious to carry on intelligent conversation. The patients have no toxicity and feel fine on awakening immediately or soon after they reach their room. They have little or no nausea or vomiting, little or no shock and practically no postoperative complications. This method of anesthesia requires no complicated costly anesthesia machines and it can be administered by an unskilled anesthetist, which is of especial importance in wartime, when transportation facilities are limited and the lack of specially trained anesthetists must be faced.

Treatment of Lung Abscess—The decision whether surgical drainage is indicated in pulmonary abscess hinges on two factors: the accuracy with which the future course of development can be anticipated, that is, the likelihood of spontaneous cure, and the safety of the technique with which the transpleural drainage is carried out. Both problems are discussed by Sanger as they came up in 21 cases, 19 of which were treated by a modified one stage method of external drainage. Surgical intervention should be carried out as soon as it is evident that bronchial drainage is unsatisfactory. Medical treatment should be abandoned if the temperature remains elevated if roentgen study shows progress of the lesion and if cessation of the sputum without abatement of symptoms indicates occlusion of a heretofore drainage bronchus. Transpleural drainage is indicated if the abscess is near the pleural surface, if it is possible of being localized accurately and if the procedure does not endanger complications. The mortality rate for the series was only 4.75 per cent although nine to five hundred and forty days has elapsed between the diagnosis and the institution of external drainage.

Diphtheric Heart Disorders in Children—Neubauer reports 100 cases of diphtheria in which there were myocardial lesions. The disorders fell into three groups: lesions of the heart musculature, abnormalities of rhythm and interference with conductivity. The chief clinical signs of the myocardial lesion were listlessness, pallor and increase or decrease in the pulse rate. Albuminuria may be found and if pronounced, is a grave prognostic sign. In the electrocardiogram alterations of the T wave, ST stretch or of both were often found. The abnormalities of rhythm may be sinus tachycardia, bradycardia or arrhythmia or extrasystoles. Interference with conductivity may be caused by partial or complete auriculoventricular block. Partial bundle branch block was present in 19. This, as well as partial auriculoventricular block, can be definitely diagnosed only by electrocardiography. Complete bundle branch block was present in 4. The electrocardiogram has shown that auricular fibrillation not only occurs in severely damaged hearts but may also be seen as a transitory phenomenon in children whose heart muscle is not damaged. Transitory auricular fibrillation may arise in children during diphtheria and may last a few hours or a few days. No abnormal clinical signs can be detected either before or after the attack and the patient is not disturbed or distressed. The prognosis is good. The electrocardiogram shows typical auricular fibrillation but there are no other signs of myocardial damage. The prognosis of auricular fibrillation in the severely damaged heart is poor, especially in those cases in which congestion was present before the fibrillation started. Death from diphtheric heart disorders in children may sometimes occur with startling suddenness in the first ten days of the disease. This often happens in severe cases of the nasopharyngeal type due to the gravis strain of the organism. The fatal issue is usually brought about by gross myocarditis, acute complete heart block or ventricular tachycardia. An electrocardiographic investigation is desirable in the treatment of any case of diphtheria other than the mildest and especially when there is reason to suspect myocardial damage. When evidence of a myocardial lesion has been found the patient should not be discharged until the electrocardiogram has returned to normal.

Pulmonary Tuberculosis in Servicemen—An analysis of 300 consecutive cases of pulmonary tuberculosis among servicemen by Crawford reveals the need for more detailed examination of men prior to enlistment, as two thirds of the cases

could in his opinion, have been detected at the initial medical examination had roentgen study been included as a routine procedure at the recruiting boards. Only 48 of the patients had a suggestive personal or family history. Criteria for further investigation usually adopted by medical boards, while important are unreliable for detecting all but a small proportion of the total number suffering from pulmonary tuberculosis. The admission of such men to the services is uneconomic. They constitute a constant danger to other members of the troop. Since roentgen investigation is the only reliable procedure for detecting clinically unsuspected pulmonary tuberculosis it is hoped that the Horder committee will reconsider the problem in the light of this and other recent studies. Manufacturers of apparatus would probably be willing to set up centers and furnish teams for the detection of tuberculosis by mass methods. The results would amply repay the expenditure involved.

Spondylitis Deformans in Relation to Fluorine and General Nutrition—The frequency of 'round back' among children and adults in areas where mottled enamel was prevalent prompted Kemp and his associates to obtain roentgenograms of the spines of such subjects. As a toxic factor would be most liable to produce this change during the most active phase of bone growth and in situations of stress and strain, the spines of children were studied. Disturbances in the natural ossification of the spines of the 22 children examined were very common. Though some of the defects probably heal or improve, many young adults were found with similar deformities and with early signs of spondylitis deformans (spondylitis osteoarthritis). Dental fluorosis was commonly associated with such changes but there is no evidence to prove that fluorine is solely responsible. Similar changes, though less definite, were demonstrated in children showing no signs of dental fluorosis and not all children with severe dental fluorosis had changes in the spine whereas some with only slight mottling showed significant deformities. The authors believe that fluorine in the water supply may influence the development of such defects especially when it is associated with defective nutrition. The roentgen changes are similar to those described by Scheurmann in adolescent kyphosis but none of the authors' patients had symptoms. They believe that spondylitis deformans (spondylitis osteoarthritis) may be the result of progressive degeneration during life of malformations acquired in youth. If this is so such changes should be preventable. Proper posture during physical training would be useful. Early treatment of this spinal condition among children whose general nutrition is already being improved by the addition of milk and school dinners. Fluorine in soil and water in association with defective nutrition may favor such maldevelopment.

Use of Blood from Universal Donor R. Bucher—p. 318

Use of Blood from Universal Donor—Bucher points out that the use of blood of the universal donor group O has been known to result in agglutination, hemolysis, shock and anemia. Schmidt and Willenberger have stressed that in view of the presence of agglutinins in O blood the term 'universal donor' can be applied only in a restricted sense. They demonstrated that O blood with a high agglutination titer can be given to recipients of other blood groups without complications, provided the transfusion is made slowly, only a small quantity being transfused, and provided the recipient is not exsanguinated or cachectic, so that the transfused blood is rapidly diluted. Severe shock may follow if large quantities of such blood are transfused rapidly and into exsanguinated patients. Bucher believes that, if undiluted group O blood is to be transfused into recipients of different blood groups, it would be advisable to determine first the agglutination titer against corpuscles of groups A and B. He describes a simple experiment which demonstrates that the use of suitable blood, which, however, is of a foreign blood group, may cause agglutination of the recipient's blood corpuscles already in the cubital vein. For this reason blood from a universal donor should be diluted to half with isotonic solution of sodium chloride before transfusing it into persons of other blood groups. In the undiluted form, blood of group O should be given only to group O recipients. The agglutination rapidly is reduced by one half in the half diluted serum and thus the infused blood becomes already mixed in the right side of the heart before the agglutination of the recipient's erythrocytes can take place. Transfusion can be done rapidly and without danger when using diluted universal donor blood for other blood groups. This applies particularly to the treatment of severe acute loss of blood when no blood of the same group is available. Whole blood of the same blood group is to be preferred. Plasma or serum of blood group AB and agglutinin free mixed plasma may be infused rapidly in the undiluted state. The biologic test of Oehlecker is indispensable in all cases.

Transient Pulmonary Shadows—Matte and Correa report histories of 6 children between 6 and 12 years of age in whom pulmonary shadows were discovered associated with comparatively mild symptoms such as cough, coryza, headache and slightly increased temperature. The well being and appetite were satisfactory. Search for tubercle bacilli was negative. The shadows disappeared in the course of from one to three weeks. The shadows were apparently nontuberculous in character. Had it not been for the circumstance that 4 of the children were in a sanatorium, that 1 was the son of a doctor and that the sixth had a glomerular nephritis, all conditions which implied continuous medical attention, the entire evolution of these shadows would have escaped detection. In 5 percussion was negative, in the sixth the dullness was limited, and few rales were detected in some. The author concludes that the children had a mild influenza in the course of which a transient pulmonary process developed which caused almost no symptoms and only a temporary roentgenologic shadow. Numerous observers have encountered similar shadows not only in influenza but also in measles, scarlet fever, whooping cough, typhoid, chickenpox, asthma and other conditions.

Dysentery in Camps—Dotzer and Schuller state that in October 1939 a large number of men were brought into a camp without quarantine enforcement or an immediate thorough medical examination. The newly interned were separated from the other part of the camp (B) by a wire fence. Cases of diarrhea appeared among the newly interned in part A. Safety measures were instituted as in bacterial intestinal disorders, but the enforcement of these measures encountered difficulties. The incidence of diarrheal disorders increased and the same type of disorder appeared in the other part of the camp. The diagnosis of dysentery was verified by bacteriologic examination. Dysentery strains of types Y and E were detected. They had a low toxin content. The detection of the same types of dysentery bacilli in both parts of the camp (A and B) and the time of appearance suggest that the disease was introduced by the newly interned men. In their part of the camp (A) the disease spread with great rapidity. To prevent dissemination of infectious material beyond the camp, ditches were dug around it and were filled with chlorinated lime. Although the detected types of dysentery bacilli had a comparatively low toxin content, the clinical aspects were those of a severely toxic dysentery. Necropsies disclosed extensive ulcerations and necroses in the entire colon and in parts of the small intestine. In the other part of the camp (B) the epidemic presented a much milder course. The patients had mucosanguineous stools, but the temperature was only slightly increased. The average duration of dysentery was thirteen days, but in many cases it lasted only six days. Necropsies did not disclose as severe lesions as had been found in the other part of the camp. The author ascribes the difference in the clinical course in the two parts of the camp to the differences in the general condition of the inmates and to disregard for bodily hygiene on the part of the inmates in section A of the camp. According to Kruse's suggestion the bacteriologic examinations were made by means of smears directly from the ampulla recti. Elimination of bacilli continued after the termination of the attack for from three to thirty days. To shorten the period of excretion of bacilli irrigations were made with rivanol and soap solution and the use of dysentery phages. Of 24 refractory carriers, 12 were treated with dysentery bacteriophages and the other 12 with rivanol or soap solution. In those treated with dysenteric phages the bacilli disappeared from the feces within a week whereas 4 of those treated with rivanol and soap solution continued to eliminate dysentery bacilli.

Meckel's Diverticulum—Heyn and Dohnert cite histories of 2 soldiers, aged 24 and 23, with severe abdominal symptoms. The first patient was operated on with a diagnosis of ileus. An adhesion which had constricted several intestinal loops was severed. A diverticulum came into view, which was covered with pus. The patient died and necropsy indicated that death was due to peritonitis. The second patient was operated on with a diagnosis of acute appendicitis. The appearance of the appendix did not explain the severe abdominal symptoms. Examination of the small intestine revealed a severely inflamed diverticulum 40 cm proximal to the cecum. It had a perforation at the base through which intestinal contents escaped. The diverticulum was resected. The postoperative course was complicated, but the patient recovered. Microscopic examination of the diverticulum disclosed that it was lined with gastric mucosa, that a peptic ulcer had developed and that the ulcer had perforated.

Recent Advances in Vitamins Vitamin B₆ or Pyridoxine O Correa—p 445

Transient Pulmonary Shadows—Matte and Correa report histories of 6 children between 6 and 12 years of age in whom pulmonary shadows were discovered associated with comparatively mild symptoms such as cough, coryza, headache and slightly increased temperature. The well being and appetite were satisfactory. Search for tubercle bacilli was negative. The shadows disappeared in the course of from one to three weeks. The shadows were apparently nontuberculous in character. Had it not been for the circumstance that 4 of the children were in a sanatorium, that 1 was the son of a doctor and that the sixth had a glomerular nephritis, all conditions which implied continuous medical attention, the entire evolution of these shadows would have escaped detection. In 5 perscussion was negative, in the sixth the dullness was limited, and few rales were detected in some. The author concludes that the children had a mild influenza in the course of which a transient pulmonary process developed which caused almost no symptoms and only a temporary roentgenologic shadow. Numerous observers have encountered similar shadows not only in influenza but also in measles, scarlet fever, whooping cough, typhoid, chickenpox, asthma and other conditions.

Dysentery in Camps—Dotzer and Schuller state that in October 1939 a large number of men were brought into a camp without quarantine enforcement or an immediate thorough medical examination. The newly interned were separated from the other part of the camp (B) by a wire fence. Cases of diarrhea appeared among the newly interned in part A. Safety measures were instituted as in bacterial intestinal disorders, but the enforcement of these measures encountered difficulties. The incidence of diarrheal disorders increased and the same type of disorder appeared in the other part of the camp. The diagnosis of dysentery was verified by bacteriologic examination. Dysentery strains of types Y and E were detected. They had a low toxin content. The detection of the same types of dysentery bacilli in both parts of the camp (A and B) and the time of appearance suggest that the disease was introduced by the newly interned men. In their part of the camp (A) the disease spread with great rapidity. To prevent dissemination of infectious material beyond the camp, ditches were dug around it and were filled with chlorinated lime. Although the detected types of dysentery bacilli had a comparatively low toxin content, the clinical aspects were those of a severely toxic dysentery. Necropsies disclosed extensive ulcerations and necroses in the entire colon and in parts of the small intestine. In the other part of the camp (B) the epidemic presented a much milder course. The patients had mucosanguineous stools but the temperature was only slightly increased. The average duration of dysentery was thirteen days but in many cases it lasted only six days. Necropsies did not disclose as severe lesions as had been found in the other part of the camp. The author ascribes the difference in the clinical course in the two parts of the camp to the differences in the general condition of the inmates and to disregard for bodily hygiene on the part of the inmates in section A of the camp. According to Kruse's suggestion the bacteriologic examinations were made by means of smears directly from the ampulla recti. Elimination of bacilli continued after the termination of the attack for from three to thirty days. To shorten the period of excretion of bacilli irrigations were made with rivanol and soap solution and the use of dysentery phages. Of 24 refractory carriers 12 were treated with dysentery bacteriophages and the other 12 with rivanol or soap solution. In those treated with dysenteric phages the bacilli disappeared from the feces within a week, whereas 4 of those treated with rivanol and soap solution continued to eliminate dysentery bacilli.

Meckel's Diverticulum—Heyn and Dohnert cite histories of 2 soldiers, aged 24 and 23, with severe abdominal symptoms. The first patient was operated on with a diagnosis of ileus. An adhesion which had constricted several intestinal loops was severed. A diverticulum came into view, which was covered with pus. The patient died and necropsy indicated that death was due to peritonitis. The second patient was operated on with a diagnosis of acute appendicitis. The appearance of the appendix did not explain the severe abdominal symptoms. Examination of the small intestine revealed a severely inflamed diverticulum 40 cm proximal to the cecum. It had a perforation at the base through which intestinal contents escaped. The diverticulum was resected. The postoperative course was complicated, but the patient recovered. Microscopic examination of the diverticulum disclosed that it was lined with gastric mucosa, that a peptic ulcer had developed and that the ulcer had perforated.

Erythema Nodosum in Venereal Lymphogranuloma—Hellerstrom's studies on venereal lymphogranuloma over a number of years throw light on the problem of erythema nodosum. Erythema nodosum becomes manifest simultaneously with cutaneous allergy and, like the latter, reaches its maximum when the inguinal adenitis is most severe and there is adherence to the covering skin which is usually the case from four to six weeks after the infecting coitus. At this time Frei's intracutaneous reaction is likewise most intense. Erythema nodosum not infrequently develops after interventions that influence the allergic status. Thus it is often possible to produce erythema nodules by the intracutaneous injection of Frei antigen. The author suggests that the pathogenesis of erythema nodosum is that of a vigorous allergic activity on the part of the skin. The eruption is the manifestation and result of an allergic reaction on the part of the skin against the micro organisms and probably also their allergens which reach the skin by the hematogenous route from the primary focus. The author's opinion is supported by his intravenous administration of Frei's antigen which elicits a protracted allergic reaction and which may provoke erythema nodosum. Erythema nodosum occasionally develops in surgical operations, in the course of which allergenic substances may accidentally enter the blood stream. The author believes that for the study of these problems venereal lymphogranuloma is a 'model disease' and offers better possibilities for investigation than does tuberculosis. Erythema nodosum is a morphologic but not an etiologic entity. Various agents may elicit the disease.

Oscillometry During Work in Neurocirculatory Asthenia—Christensen studied patients with neurocirculatory asthenia with the aim of developing a functional test which might furnish information regarding their fitness for military service. Krogh's cycloergometer was used. Oscillometric measurements were made with the optic self-recording oscillograph of Eldahl. The oscillometric curve gives information regarding the arterial pressure and the strain on the arterial wall. Observations were made on healthy subjects and on patients with neurocirculatory asthenia. The blood pressure and pulse rate variations during work agree with those obtained by other investigators. The altered reaction of the large arteries during exertion have not been previously observed. In connection with muscular work there occurs dilatation of the vessels in the exercised muscles, which might cause a fall in the arterial pressure if the organism did not at once empty its blood reservoirs. This increase in the circulating blood, combined with the decreased peripheral resistance in the working muscles, will alleviate the diastolic filling of the heart and will thus be capable of producing the required augmented output of the heart in sound persons. Since it is chiefly the blood flow through the working muscles which has to be augmented, it might be thought that a compensatory contraction of the arteries outside the working extremities would take place so that a larger part of the cardiac output would be available for the working muscles. The oscillometric curves demonstrate, however, that this does not happen in healthy subjects. In neurocirculatory asthenia, in which the heart is possibly small, drop shaped or pendulous, it might be thought that the heart requires a higher pressure in the central veins in order to increase its beat volume. This

high pressure in the central vein might be obtained by driving a larger part of the blood through the working muscles where the resistance is less than in the rest of the arterial tree. Experiments have proved that the arteries outside the working extremities are contracted during work in these patients. The author also cites observations by Munch-Petersen and thinks that the demonstrated reaction is due to hyperirritability in the vasomotor centers even if the reaction demonstrated facilitates the circulation during work.

Renal Blood Flow in Health and in Hypertension or with Renal Disease—Steinitz directs attention to the non-surgical method of determination of the renal blood flow which was described by Chasis and his collaborators. The mean values of renal plasma flow (diodrast clearance) and of glomerular filtration (mulin clearance) detected by him were in the same range as those reported by Chasis and his collaborators, Ranges, Goldring and Smith. In 4 out of 6 cases of essential hypertension the renal blood flow and the glomerular filtration were found within the normal range. This indicates that a decrease in the renal blood flow is not a necessary and characteristic attribute of essential hypertension and that it is advisable to continue to differentiate essential hypertension as a distinct entity from renal hypertension. The author studied the renal blood flow and the glomerular filtration also on patients with malignant hypertension, with acute nephritis and with the nephrotic syndrome. The method discloses that the renal form of hypertension may take two courses: either some glomeruli are entirely excluded by the pathologic process and in the functioning ones the tonus of the afferent and efferent vessels is regulated so that the filtration remains almost normal, or the process is localized chiefly in the vasa efferentia, which induces a compensatory increase of filtration and uric acid elimination. In the 2 examined cases of acute nephritis, the filtering surface was greatly reduced. It can be concluded from the low filtration fraction that in the still functioning renal units the tonus of the vasa efferentia does not dominate over that of the vasa afferentia. In the cases with the nephrotic syndrome the filtration fraction is near the lower limit of normality which indicates that a relatively great renal blood flow is accompanied by a normal or low glomerular filtration. The author suggests as a possible explanation of this relative hyperemia a decrease in the tonus of the vasa efferentia which in turn elicits a decrease in the filtration pressure analogous to the hyperemia brought on by fever.

Desoxycorticosterone Acetate—Jonas and Jelinek present a critical evaluation of desoxycorticosterone acetate therapy in Addison's disease. Their evaluation is based on reports in the literature and on their own experiences. There is as yet no agreement whether this synthetic preparation is a complete substitution for adrenal insufficiency. The disturbances in the carbohydrate metabolism are less amenable to treatment than are other metabolic defects. This is of decisive importance for the restoration of the muscle force. The working capacity of a patient with Addison's disease depends to a great extent on the type of occupation. The presence of a tuberculous process is often decisive for the course and the ultimate fate of the patient. Intercurrent fevers, surgical interventions and pregnancy may also interfere with the therapeutic results. Edema and hypertension are not manifestations of the toxicity of the adrenal preparation but are caused by the simultaneous administration of unusually large quantities of sodium salts. It is now regarded as incorrect to prescribe a potassium deficient diet for patients undergoing treatment with the adrenal preparation. The authors observed a noticeable modification of the different metabolic processes and an improvement in the general condition and in some clinical symptoms following the prolonged administration of large doses of the synthetic adrenal hormone. The implantation of tablets of crystalline desoxycorticosterone acetate produced favorable results in 2 cases. The improvement is approximately like that obtained with daily injections of 10 mg. The depot therapy with the synthetic preparation was accompanied neither by an increased administration of sodium salts nor by a reduction in potassium salts. Administration of large doses produced no unfavorable results.

Book Notices

Digest of State and Federal Laws Dealing with Prostitution and Other Sex Offenses with Notes on the Control of the Sale of Alcoholic Beverages as It Relates to Prostitution Activities Compiled under the direction of Bismarck Johnson A.B. LL.B. Associate Director in Charge of Legal and Protective Measures American Social Hygiene Association New York By George Gould A.B. LL.B. M.A. Legal Consultant American Social Hygiene Association and Roy I. Dickerson LL.B. LL.M. Executive Secretary Cincinnati Social Hygiene Society Cloth Price \$5.00 Pp 163 New York American Social Hygiene Association Inc., 1912

In response to many requests received from officials, voluntary agencies and state and community leaders, the American Social Hygiene Association has compiled this digest of state and federal laws dealing with prostitution and other sex offenses. Arranged by states, the material is grouped under four main headings: (1) Activities of Exploiter of Prostitute Prohibited, (2) Activities of Prostitute or Her Customer Prohibited, (3) Other Sex Offenses Prohibited and (4) Supplementary Laws, including laws concerning the sale of alcoholic beverages. This volume is complementary to a digest published by the same association in 1940 and revised as of July 15, 1941, covering the laws and regulations that have been enacted or promulgated relating to the prevention and control of syphilis and gonorrhea. Together they make available in a convenient form digests of all the legal measures, both state and federal, that exist to deal with those diseases that are responsible for four times more disability than any other single cause in the army. Both digests have been carefully prepared, and every effort has been made to achieve accuracy and completeness. They afford a ready means, first, of determining what legal remedies are available in each state to reduce the incidence of syphilis and gonorrhea and, second, of comparing the legal remedies of one state with those of other states. As reference volumes, both the digest of laws relating to prostitution and the digest of laws relating to the correlated subject of the venereal diseases are distinct and timely contributions.

Skin Grafting from a Personal and Experimental Viewpoint By Earl Calvin Padgett M.D. F.A.C.S. Professor of Clinical Surgery University of Kansas School of Medicine Kansas City Kansas Cloth Price \$15.00 Pp 149 with 65 illustrations Springfield Illinois & Baltimore Charles C Thomas, 1942

The author and Professor Hood of the University of Kansas have perfected a calibrated mechanical device for cutting skin at virtually any predetermined thickness. This volume presents a brief for a "three quarter thickness" graft, which can be cut with ease when this ingenious device is used. The advantages of this somewhat thicker type of graft over the intermediate grafts of Thiersch and Blair are outlined. The first three chapters include a brief historical outline of the landmarks in the development of this phase of surgery and a discussion of the fate of autogenous, homo and hetero transplants. Remarks on the preservation and histology of skin grafts are also included.

The author gives three reasons to support the view that the "three quarter thickness" graft has certain advantages over the Thiersch type of graft:

- 1 The degree of contraction of the base of a wound is proportional to the thinness of the overlying graft. In some areas the graft may contract as much as 60 per cent.
- 2 The final appearance of the "three quarter thickness" is cosmetically superior to the thinner grafts.
- 3 It does not, on the other hand, possess the disadvantages of the full thickness graft. If a full thickness graft is applied to a granulating surface, it is seldom that a take is obtained.

The ingenious dermatome of the author provides a method for cutting a uniform sheet of skin at a predetermined level with mechanical precision. Whereas the Thiersch graft as cut with the hand knife may vary considerably, the dermatome graft may be cut accurately in any range from 0.008 to 0.024 inch. (A full thickness skin graft in an adult varies in thickness from 0.032 to 0.040 inch. The "three quarter thickness" graft is cut at a level 75 to 95 per cent of the thickness of the skin.)

The chapter describing the dermatome unfortunately gives little information on the actual technique of its use. One desiring details as to the method of operation will have to look elsewhere. Likewise the book lacks the necessary detail to be recommended as a textbook for student use.

If the sulfonamides are of value in this type of surgery either in the preparation of recipient areas or for application at the time of grafting, the author is perhaps guilty of an important omission, as there is no mention of this subject. The use of split thickness grafts in the primary treatment of war wounds in which there has been avulsion of skin (compound fractures and so on) does not receive any comment. The careful attention of the publisher to details of printing and design has resulted in a book with physical and artistic qualities deserving of praise.

A Monograph on Adolescent Spondylitis or Ankylosing Spondylitis: The Early Diagnosis and its Treatment by Wide Field X Ray Irradiation By S. Gilbert Scott M.R.C.S. L.R.C.P. F.R.C. Consulting Radiologist to the London Hospital London. Published under the auspices of the Nuffield Wide Field X Ray Therapy Research Research No. 1. Cloth Price \$1.10 Pp 192 with 21 illustrations New York & London Oxford University Press 1942

The author is well known for his book "Radiologic Atlas of Chronic Arthritis (The Hand)." Scott describes a type of patient who if taken in time can be saved but if neglected either by misdiagnosis, ignorance or neglect will become what is called a 'horrible example,' which is illustrated in the frontispiece as a "spondylitic wreck." The so-called adolescent kyphosis is not a specific pathologic entity but in reality an excessive kyphosis associated with the final stages of adolescent spondylitis. It is imperative that the syndrome be recognized because it can be completely arrested by the use of wide field roentgen therapy during the prespondylitic stage. Any type of spondylitis that may lead eventually to deformity is called spondylitis deformans. Spondylitis that attacks the young adult is called ankylosing spondylitis, which Scott prefers to call adolescent spondylitis. Spinal arthritis of the elderly or aged patient is known as spondylitis osteoarthritis or "old man's spondylitis." Scott suggests the term adolescent spondylitis for ankylosing spondylitis that attacks the young adult. In eight years as physician-radiologist to the British Red Cross Clinic and Charterhouse Rheumatism Clinic he has collected the records of 300 established cases. The onset is insidious, extending over a period of five to seven years before the appearance of spinal symptoms. It attacks the young, healthy athlete, usually the male. The only clinical sign may be pain in the hip, ankle or in fact of any part except the back or the sacral region. Infective changes are always present in the sacroiliac joints. During the active stages pain is not felt either over the sacroiliac joints or in the back. Bony ankylosis of the sacroiliac joints is nearly always complete by the time the clinical signs of spondylitis appear. The sacroiliac joints always present pathologic changes.

The painful and stiff spine so characteristic of spondylitis described in textbooks represents the last and not the first chapter of the disease. The author describes the advances in obtaining a complete roentgenographic record of sacroiliitis. He finds that stereoscopic films are of little advantage and that the most reliable information is obtained from roentgenograms taken in the strict standard position. The author is responsible for the treatment of sacroiliitis, which is synonymous with what Americans call sacroiliac disease or sacroiliac arthritis. He describes the normal sacroiliac joint and illustrates it with gross anatomic specimens and roentgenograms.

If this disease is to be eradicated, radiologists must assist by making themselves familiar with the early changes in the sacroiliac joints associated with the prespondylitic phase. Every physician should be able to recognize the characteristic clinical history. Attacks of rheumatic pains referred not to the back or sacroiliac joints but to various parts of the body, occurring in a young adult over a period of years, should always suggest a radiologic study of the sacroiliac joints.

There is a short chapter on the interpretation of the roentgenograms of the sacroiliac joints in the first, second and third

stages of the disease. Differential diagnosis considers tuberculous sacroiliitis, tuberculous hip, sacroiliitis associated with spondylitis, tuberculous disease of the hip joint and hip symptoms associated with spondylitis.

Introduction to the Microtechnique of Inorganic Analysis By A. A. Benedetti-Pichler, Dr. Techn. Sc., Assistant Professor of Chemistry, Queens College, Flushing, N. Y. Cloth. Price \$3.50. Pp. 302 with 84 illustrations. New York: John Wiley & Sons Inc. London: Chapman & Hall Limited. 1942.

The systematic development of inorganic microchemistry is attributed mainly to the efforts of F. Enich, with whom the present author was associated as a student. The universality of Enich's thinking, acuteness of observation and the applicability of his experimental techniques have resulted in an international school of microchemistry. The present book is based largely on the fundamental principles of the Enich school.

This volume replaces the 'Introduction to the Microtechnique of Inorganic Qualitative Analysis' by A. A. Benedetti-Pichler and W. F. Spikes. It is not intended as a comprehensive treatise on microchemistry but rather as a working text for those who wish to acquire a general knowledge of the techniques and apparatus involved in handling small quantities of material. For this purpose it serves admirably as the book has evolved from the author's classroom experience in teaching microchemistry at Washington Square College and Queens College. It fulfills the student's need for sound basic training together with sufficient information to enable him to apply the knowledge to specific problems.

A description of apparatus for general use is treated in the first forty pages of the text. There follow 128 pages on qualitative analysis in which is included information on spot tests, slide tests, fiber tests, test tube tests and bead tests with selected reactions which have been found through long experience to yield consistently good results. The section on microtechnique of qualitative analysis includes mechanical manipulation, work on microscope slides, work in capillaries, observation of color, centigram procedures, milligram procedures and microgram procedures. A scheme for the separation and identification of the copper and arsenic group of elements is included under milligram procedures. Besides providing a working plan for these separations, the scheme illustrates what may be accomplished in the separation of small amounts of material and is a guide to the application of macro-analytic schemes to micro quantities.

A section on quantitative microanalysis (sixty-three pages) treats centigram, milligram and microgram procedures both in gravimetric and in titrimetric analysis.

Numerous illustrations of apparatus and techniques are included. The material is well organized and presented in a logical, concise style. References to the original literature are given for a large number of the tests, techniques and apparatus. The appendix includes a bibliography and sufficient information for setting up a basic course in inorganic microanalysis.

The Ophthalmic Formulary Compiled by G. Griffin Lewis, M.D., F.A.C.S., Oculist to the Crouse-Ingling Hospital, Syracuse. Containing the Favorite Prescriptions of Prominent Oculists from All Parts of the World. Fabrikoid. Price \$3.50. Pp. 167. Springfield, Illinois: C. Baltimore. Charles C. Thomas. 1942.

The author has collected from standard textbooks and works on therapeutics and through personal correspondence what he describes as "the favorite prescriptions of prominent oculists from all parts of the world." The prescriptions are listed under headings comprising the conditions or purposes for which they are employed, which are arranged alphabetically. Use is made of both the metric and the apothecary's system, according to the source from which the prescription was obtained. The source is credited to the name of the contributor without reference, and apparently without any implication that the prescription was original with the contributor named. Blank pages are left for additions by the reader. The author has included a number of remedies which seem strange to the present generation. Thus it will be news to many that fluid-extract of aconite in boric acid solution was ever used locally in conjunctivitis, or a combination of tincture catechu and aquae laurocerasi in blepharitis. It is interesting to note that

M. Ramsay employed quinine internally for such conditions

as chronic glaucoma and retinitis pigmentosa. The use of oil of capcut and brandy for flatulence after the cataract operation might, on second thought, prove effective, as one dose of this mixture would be calculated to restrain the patient from indulging his infirmity. One misses certain modern drugs of undoubted value. Thus under "anesthetics, local," alpin is included, but neither pontocaine nor butyn. Neither epinephrine nor its newer derivatives are mentioned as mydriatics. A number of misprints have escaped the proofreader. Following the formulary are twenty-six pages of ophthalmic materia medica, in which drugs are listed alphabetically, with a brief note as to the uses of each. The index lists only conditions for which drugs are employed. It is not the author's intention to present his own conclusions concerning therapeutics and he has not done so. For the ophthalmologist or general practitioner who has no very definite ideas on the subject and who wishes to find quickly what remedies have been used in certain conditions, the book affords a handy source. What results he will obtain by employing some of the prescriptions he will find here; the reviewer is not prepared to state. The publisher has produced a very attractive little volume.

Synopsis of Blood Diseases By A. Hines, M.D., M.R.C.P., Physician St. Mary's Hospital for Women and Children, London. Fabrikoid. Price \$2.75. Pp. 120 with 4 plates. Philadelphia: Bliston Company. 1942.

This small handbook is interesting and is quite a departure from other recent books on hematology. In fifteen chapters concise, minimal descriptions of the symptoms and signs, the blood changes, the pathology and the treatment of the standard diseases of the blood and blood-forming organs and certain systemic conditions are given. There are a number of tables and a folding page giving a description of the size, cytologic characteristics and staining reaction of each kind of blood cell. The book may suffer at first by comparison with the larger hematology books but for its intended purpose, a hematology book for physicians, general practitioners and students in which 'no attempt has been made to go into details that are of interest only to hematologists and clinical pathologists,' it has a definite use. A glossary of hematologic terms is given. The list of reference books under the heading of 'Literature' is rather scanty and is predominantly British. Because of the absence of the theoretical and controversial material, this is a handy reference book for rapid consultation.

Handbook of Medicine for Final Year Students By C. F. Walker, M.D., M.R.C.I. Second edition. Cloth. Price 15s. 1p. 320. London: Syburo Publications Ltd. 1942.

The preface states that this handbook is intended for senior students and for practitioners doing hospital work or revising for higher examinations. It is aimed at assisting the student in selecting what will be important to him not only in his final examinations but in actual practice. To the reviewer's mind the material in this book is far too condensed and it is difficult to believe that it can contain anything which a well-trained student or practitioner would not already know or could not find more adequately discussed in modern and readily available textbooks. The evident fact that there is a demand for this type of compilation is presumed to be a reflection of continued overemphasis on examinations rather than on sound fundamental training for medical practice.

Solving School Health Problems The Astoria Demonstration Study. Sponsored by the Department of Health and the Board of Education of New York City. By Dorothy B. Nysswander, Ph.D., Director of the Study. Cloth. Price \$2. Pp. 377. New York: Commonwealth Fund. London: Oxford University Press. 1942.

This book reports how the actual staff of the community functioned and how, by teamwork and cooperation of all concerned with school health work, they can do the best possible job with the tools at hand. Actual practices were studied and, if found wanting, changed, restudied and changed again. The sixteen chapters include adequate, dispassionate discussion of the school physician and his job, teacher participation, educational opportunities of the nurse as well as her daily tasks, keeping school medical records alive and the private physician and the school health program. For those physicians who take seriously their work in school health this book is ideal.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

BED REST AND EXERCISE RESTRICTIONS AFTER CHILDBIRTH

To the Editor—There is an acute shortage of beds in the hospitals for maternity patients in this district. This brings up the question of how long it is necessary for patients to stay in bed after delivery. What are the reasons for staying in bed any certain length of time and how long should it be?

Nathan J. Barlow MD, Bell Calif

ANSWER—The question of how long patients should be required to remain in bed after delivery has been debated back and forth for years without having been authoritatively settled. The general rule in this country and in Great Britain has been to keep them in bed until the uterus has involuted to the point where the fundus is no longer palpable, or barely so, above the symphysis pubis, this being usually from the seventh to the ninth day.

To allow a woman out of bed earlier than this invites undue weight and strain on the overstretched but involuting ligaments as well as on the fascial and muscle supports of the pelvic floor leading to prolapse of some degree and retrodisplacements of the uterus. Moreover, a patient with a sutured perineum requires at least a week for union and healing, if poor results are to be avoided. These are mechanical reasons for rest in bed for a week to ten days after delivery.

Late hemorrhage infection and delayed or prolonged convalescence with possible interference to the breast milk supply, especially if anemia is present, are less tangible clinical reasons against early rising.

All of this is bound closely to the fact that the average woman displays little or no common sense about her care after confinement and this is perhaps, a psychic reason why she should be restrained to her bed for a reasonable period and then confined on the second floor, without stair climbing until about four weeks post partum. Stair climbing in itself does no harm, but this is a convenient way of preventing too early a dash to bridge parties or to the laundry tubs, as the case may be. So many will disregard instructions anyway that it is best to make them maximum.

Several years ago Gauss in Freiberg of the "twilight sleep" fame advocated having puerperal women out of bed on the second or third day. The average woman in that community looked like an old woman at 40 and little has been heard elsewhere of his theories.

A compromise for overcrowded maternity hospitals might be to discharge patients by ambulance to their homes on the seventh or eighth day with printed, not oral, instructions about their further care, augmented by visits from public health nursing services, if available.

DANGEROUS ANESTHETIC METHOD

To the Editor—The following mode of brief anesthesia has been used as a joke played by boys on one another. Please tell me whether you consider it dangerous. If not might it not be used for such purposes as to open abscesses and other brief procedures in the backwoods if one has no other method at hand. The subject takes a long series of deep breaths ending by holding his breath. The other party seizes him around the chest from behind with both arms and squeezes his chest tightly. The subject quickly loses consciousness.

M D Florida

ANSWER—This method of producing loss of consciousness is a modification of the early experiment of Valsalva (1666-1723) and was studied by Luckhardt and Johnson (*Am J Physiol* 83:642 [Jan], 84:453 [March] 1928). Through an analysis of the effects of raised intrapulmonic pressure in dogs and man they showed that this brings about a slowing of the heart by stimulating the cardiorespiratory center reflexly, which also comes as a result of direct central asphyxia. The authors were able on human subjects to cause a primary drop in blood pressure of 50 mm of mercury with a secondary rise of 24 mm above normal. Modifications of the Valsalva experiment of raising the intrapulmonic pressure have been employed clinically in cases of tachycardia in an attempt to reduce the heart rate. All authors are agreed that the procedure is dangerous to patients with a weakened heart. To quote from Luckhardt and Johnson

"If in the supine position the systolic pressure can be more or less suddenly dropped 40 to 72 mm of mercury, such compression causes most probably an even greater drop in pressure when the person is in an upright position, as is usually the case. The giddiness occasioned in the course of the compression results from the impairment of the arterial circulation through the brain, and if in a given individual the compression is so marked and prolonged that the left heart receives little or no blood, complete unconsciousness (anesthesia) results because of a complete absence of cerebral circulation. The general passive congestion is, to say the least not beneficial or entirely innocuous. But what is more deleterious is the sudden change in blood pressure from a very low point to one exceeding the normal some 30 mm or more (man). The more or less sudden and pronounced after-fling may easily lead to rupture of arterioles especially if the latter are already weakened by disease. The sensation of fullness in the head, headache, nausea, ataxia and vertigo, which are experienced immediately on release of the compression and which may last for hours, are cerebral disturbances resulting from mild injury to the nervous tissues. The experiment is harmful when performed on healthy individuals, it may prove disastrous when performed on an individual having even slight myocardial or vascular lesions." It is doubtful if this method of anesthesia could be used any more effectively than choking to the point of unconsciousness or a knockout blow on the head for minor surgery in the 'backwoods,' and it is probably just about as dangerous.

PREVENTION OF SKIN IRRITATION FROM LIME DUST

To the Editor—An industrial plant uses large quantities of lime. The lime is received in bags and the men who handle these bags get a considerable quantity of lime dust on their skin. They are protected by goggles, filter masks and gloves. The lower extremities are protected by trousers which are tied around the ankles however because of the heat it is almost impossible to get them to wear protective clothing on the trunk and most of them work stripped to the waist. The accumulation on the skin of the lime mixed with perspiration produces frequent burns of the skin particularly in the folds. Can you furnish me with information concerning some kind of protective application to the skin to prevent these burns? I had in mind the use of an ointment with petrolatum jelly as a base that could be easily and cheaply prepared in large quantities that would cling to the skin sufficiently to protect it and possibly have a neutralizing effect on the lime also. Any information or suggestions that you could give to me on this subject would be greatly appreciated.

Alfred D. Mason Jr MD Memphis Tenn

ANSWER—No cream or ointment can be expected to furnish full protection against burns of the skin from lime, but their use is advocated nevertheless. Some plain ointment materials such as hydrous wool fat or petrolatum are of some value the preference always being for that harmless material low in cost which best remains on the skin surface. The addition of boric or benzoic acid with or without cornstarch represents an advance over the base emollients only. Protective ointments are discussed in a publication by Schwartz in *Medical Clinics of North America* July 1942, page 1195. Various types of ointments are discussed together with a listing of the better known commercial preparations. In addition to the possible need for a protective ointment for these lime workers, either made up locally or obtained from commercial sources, it is desirable that the workers maintain a high order of personal cleanliness, particularly when away from work duties. Lime dusted clothing should not be worn apart from work. All lime should be removed from the skin at the end of the work period and if practical, one or more times during the work period. The application of a bland ointment to exposed areas at the end of the work period, after proper cleansing may be beneficial. In addition to the present personal protective devices mentioned in the query it may be necessary to wear petrolatum coated cotton plugs in the ears to prevent aural dermatitis. Should any lime dermatitis appear, further contact with lime should be excluded for the time being pending healing. This may not necessitate absence from work.

DIETHYLSTILBESTROL FOR KRAUROSIS VULVAE

To the Editor—Please advise how much powdered diethylstilbestrol should be incorporated in an anhydrous wool fat base for relief of kraurosis vulvae.

M D Massachusetts

ANSWER—An effective diethylstilbestrol ointment is one which contains 1 mg of diethylstilbestrol to 1 Gm of the wool fat base. This medication should be used for kraurosis vulvae with the greatest caution because of the potentially malignant changes in this lesion.

LEUKORRHEA

To the Editor—A white woman aged 30 married has complained of a vaginal discharge for the past two years. The character of the discharge varies. At times it is thick at other times thin and occasionally it isropy and blood streaked. Occasionally she menstruates about one day between the eleventh and fourteenth days of her period. The uterus is in good position freely moveable and without pain. The tubes and ovaries are apparently normal. The cervix is normal in appearance. Smear of the discharge shows many pus cells some blood cells occasionally and a great deal of mucus. There are a large number gram negative and gram positive bacteria. There are no gonococci and no Doderlein bacilli. Wet smears have been repeatedly negative for *Trichomonas vaginalis*. What is the probable cause of this discharge? What treatment can be used to eradicate it?

M D West Virginia

ANSWER—The discharge most likely is associated with ovulation. Many women have a mucous or ropy discharge during the middle days between two menstrual flows. Not infrequently the discharge is blood streaked and in some instances there is a bright bloody flow. Most women have discomfort in one or the other iliac fossae during the time of ovulation, and in some instances the pain is severe enough to be mistaken for appendicitis. There is no treatment for the prevention of midinterval pain or the vaginal discharge. If the discharge is troublesome, acid douches using vinegar or lactic acid may prove helpful. If the discharge is not enough to require the use of some form of protection and if it does not soil the clothes, nothing need be done.

IODIDES FOR SYPHILIS IN PRESENCE OF
TUBERCULOSIS

To the Editor—I should like to inquire whether potassium iodide is contraindicated as antisyphilitic therapy for a patient with tuberculosis of the skin. Also if potassium iodide would cause ulceration of a positive tuberculin reaction in a patient with tuberculosis of the skin. Information relative to these questions will be greatly appreciated.

George T. Thornhill Jr. M D Baltimore

ANSWER—There is no definite evidence to prove that potassium iodide is contraindicated as antisyphilitic treatment for a patient with tuberculosis of the skin or that it would cause ulceration of a tuberculin reaction in a patient with tuberculosis of the skin. It was formerly thought that potassium iodide breaks down fibrous tissue in the vicinity of tuberculous lesions. At one time the iodides were used extensively in the diagnosis of pulmonary tuberculosis that is, when tubercle bacilli could not be recovered from the sputum large doses of iodides were administered, following which in some cases tubercle bacilli appeared in the sputum. The conclusion was drawn that the iodides broke down the lesions and liberated bacilli. As they serve as expectorants by increasing and liquefying the secretions in the bronchial tree, it seems probable that they resulted only in liberation of mucus and other materials from the region of the lesion in which bacilli could be demonstrated. The fear of the administration of iodides to tuberculous patients has definitely decreased in the last few years. In fact, iodized oil is now frequently introduced into the bronchial tree of patients with pulmonary tuberculosis. There is no evidence that iodides given in the usual dosage have any deleterious effect on tuberculous lesions in any part of the body.

IMMUNIZATION PREPARATIONS AND LOCAL
ANESTHESIA

To the Editor—I should like to know if procaine hydrochloride 1 per cent may be added (a few drops) to immunization preparations such as for pertussis, in order to allay the pain following the injection. Would this addition not be of great aid to pediatricians if it does not interfere with immunization?

M D, Illinois

ANSWER—Pain at the site of injection of antigens such as pertussis vaccine immunizing is neither immediate nor intense when it is given into the superficial subcutaneous tissue of the upper arms so that a visible lump and transient red area of the skin result. The 1, 2 and 3 cc. of the now customary 15,000 million per cubic centimeter concentration are injected at three week intervals to minimize local reaction, retard absorption and insure the highest possible immunity response. Intradermal injection would cause a more severe local reaction. Injected intramuscularly, absorption would be quickened, with a more severe systemic (febrile) reaction, because of this the immunity response might be lessened.

Procaine hydrochloride added to the antigen would give no relief because local pain with tenderness occurs, not at the time of injection, but eight to thirty-six hours later. A small amount of acetylsalicylic acid seems helpful. Local treatment, such as wet dressings or external heat, should not be applied.

STANDARDS OF ANESTHETIC PRACTICE

To the Editor—What regulations should be followed by small hospitals regarding the administration of anesthetics, especially intravenous anesthesia?

M D Kansas

ANSWER—The Council on Medical Education and Hospitals of the American Medical Association and the College of Surgeons both recommend that an approved hospital staff must include at least one physician who serves as director of anesthetic practice in the institution. In a small institution where several physicians administer the anesthetics but do not confine their work exclusively to anesthesiology, a small committee may act in the capacity of director of the service.

Consultation with the director of the Anesthesia Service at the University of Kansas Hospital at Kansas City, Kan., should prove fruitful in solving a local problem.

SODIUM CHLORIDE OR UREA "FROST" ON SKIN

To the Editor—In severe cases of uremia a crystalline deposit sometimes occurs on the skin. I thought that it was urea or urea frost. A few days ago a colleague of mine informed me that it was sodium chloride and not urea. I shall be grateful for this information.

M D, New York

ANSWER—The salt content of sweat may lead to crystalline deposits or "frost" on the skin. However, a true "urea frost" does at times develop in severe cases of uremia, especially in cases in which diaphoretic measures have been employed. To differentiate between sodium chloride and urea crystals, some of the deposit should be scraped off and treated on a glass slide with a few drops of diluted nitric acid. Crystals of urea nitrate will be seen after evaporation of the liquid. For further tests, consult a standard textbook on biochemistry.

SUBPERICHOONDRIAL INJECTION OF ANESTHETIC SOLUTION

To the Editor—Is there any danger of a severe reaction from the use of epinephrine hydrochloride solution 1:1,000 one drop to the drachm in a 1 per cent procaine hydrochloride solution injection of a drachm or two of the epinephrine procaine solution under the perichondrium preliminary to a submucous resection?

J F Martin M D Dunn N C

ANSWER—Solutions of the strength mentioned have been injected under the perichondrium preliminary to a submucous resection with no untoward reactions.

If the medical condition of the patient to stand a submucous resection is unquestioned and indications warrant this operation, the injection of this solution may be undertaken with relative impunity.

URINARY FREQUENCY AND PSYCHOTHERAPY

To the Editor—It is discouraging to read the answer to the Ohio physician who inquired about refractory urinary frequency in a young girl (*The Journal* Sept 5 1942 p 87). So many people have belabored the use of the terms organic versus functional that I will pass this by lightly and note that all disease is organic and functional. The advice that it is desirable to exclude organic disease before concluding that the symptoms are of functional nature belongs in treatises on the history of medicine rather than in a modern medical journal. This statement is rather like saying that one must rule out all other disease before concluding that the symptoms are those of carcinoma. The symptoms of psychogenic disease are as obvious as the symptoms of other disease if one would but take the trouble to look for them. Psychogenic disorders are better diagnosed directly not indirectly and treated in their incipience. This simple rule holds for much of medicine. To expect a good result from psychotherapy after the genitourinary manipulation suggested in this case is unwarranted optimism. After considering lengthy bladder and urethral maneuvers it is concluded that if the urologic investigation reveals no abnormalities the urinary frequency must be considered as functional in nature.

Further advice is unhesitatingly prescribed for a presumed active psychogenic disorder as follows and treated by means of rest recreation suitable hobbies and mild sedatives. Having meandered atactically toward a diagnosis there would seem to be no doubt about the method of psychotherapeutic. Who in this day puts his faith in therapy of the sedative type for an intelligent young woman? Obviously the ideal method for a 16 year old honor student with psychogenic disorder would be to have her seen by an expert psychiatrist. Failing this the practitioner should take the time to talk to the patient and particularly to listen to her story which may be long and seemingly lead far afield. As in all disease he should attempt to find the cause of the symptoms. This is hardly the place for a discussion of this procedure. The reader is recommended to Levine *Psychotherapy in Medical Practice* (New York Macmillan Company 1942) in the absence of competent psychiatric help.

TREATMENT OF BURNS

WITH 2.5 PER CENT SULFADIAZINE IN 8 PER
CENT TRIETHANOLAMINE SOLUTION

MILTON ROTHMAN, M.D.

JOSEPH TAMERIN, M.D.

AND

JESSE G. M. BULLOWA, M.D.

NEW YORK

When the surface of the body has been damaged by flame, scalds or chemicals, plasma escapes from the circulating blood into the injured tissue and from the surface deprived of protective coating. The resulting hemoconcentration, if uncorrected, may prove fatal. The exposed tissues provide an excellent culture medium without the usual dermal barrier to infection.

We have treated 32 patients suffering from burns which involved up to 45 per cent of body surface as measured by the scale devised by Berkow,¹ with two deaths. These 2 patients died in secondary shock within the first forty hours. Sufficient plasma or blood was not available to counteract the hemoconcentration. One patient had the entire left upper extremity completely charred. The other had a third degree flame burn involving 45 per cent of surface, mostly the trunk. There was no evidence of sulfadiazine toxic action on physical or laboratory examination during life.

The local treatment of these patients was application of 2.5 per cent sulfadiazine in 8 per cent triethanolamine solution² in accordance with the method of Pickrell,³ modified to provide rapid formation of an eschar by desiccation of the exuded serum. The method used was as follows:

On admission of the patient to the accident ward, usual methods to combat shock are promptly instituted. These are frequent plasma infusions (as much as 2,500 cc), adrenal cortex extract (1 cc each day) and

warmth. If the clothing is adherent, it is removed under morphine narcosis by soaking the patient or part involved in a tub of water at 100 F. Usually the clothing is not adherent and can be cut away. The patient is then placed on sterile sheets, and with aseptic technique the wound is cleansed. The surgeons wear caps, masks, sterile gowns and gloves during the procedure. Blisters are opened, and loose shreds of epithelium and skin are removed. The area is again sponged with sterile water at 100 F. If all the dirt is not removed by this technique we use the suds of white soap on cotton balls. Grease is removed with ether or benzene. The entire procedure is carried out without anesthesia, rapidly and without pain. Green soap, gauze and scrubbing are not used.

The 2.5 per cent sulfadiazine in 8 per cent triethanolamine is sprayed on the surface of the wound every hour on the first day. After each application the surface of the wound is dried by fanning or, more recently, by an electric hair drier with warmed air. The same procedure is carried out every two hours on the second day, every three hours on the third day and every four hours on the fourth day. A heat cradle is used to maintain the body temperature at 90 F. Care should be taken to avoid any burns from this source. At all times aseptic technique is maintained. Physicians, nurses and visitors wear caps, masks and gowns.

A thin, pliable and translucent eschar forms in twenty-four to thirty-six hours and after the fourth day. Spraying is rarely necessary. No dressings are applied at any time. Sedatives are rarely required after the eschars are formed, and nursing care is minimal. Between the tenth and the twelfth day the edges of the eschar tend to curl, at this time wet dressings of the sulfadiazine triethanolamine solution are applied. As the eschar curls at its edges, a potential portal of entry for bacteria forms. Wet dressings of 2.5 per cent sulfadiazine in 8 per cent triethanolamine solution are applied at this stage in order to prevent secondary infection. Sometime between the twelfth and the twenty-second day the eschar will be completely separated, and its removal may be facilitated by cutting away the loose portions. When infection occurs, purulent material is readily visible because the eschar is translucent. A window is cut in the eschar to permit drainage. Wet dressings of the sulfadiazine solution are applied over the infected area until the infection has cleared. The procedure is the same for second and third degree burns. The spray has been used about the face, eyes and mucous membranes without injury. Similarly the 2.5 per cent sulfadiazine in 8 per cent triethanolamine solution is used on joints and fingers without constriction or limitation of motion. The eschar is pliable and does not crack.

Dr. Rothman is research fellow in surgery. Dr. Tamerin is associate visiting surgeon and Dr. Bullowa is visiting physician. Harlem Hospital. Miss Mildred Sommers studied the cultures. Herman Ratish is responsible for the blood level determinations. Dr. W. G. Malcolm of Lederle Laboratories, Inc., Pearl River, N. Y., supplied the sulfadiazine solution.

From the Surgical and Medical Services of Harlem Hospital, Department of Hospitals, New York, and the Littauer Pneumonia Research Fund of New York University College of Medicine and the Metropolitan Life Insurance Company.

1. Berkow, S. G. Value of Surface Area Proportion in the Prognosis of Cutaneous Burns and Scalds. *Am. J. Surg.* 11: 315-317 (Feb.) 1931.

2. The 2.5 per cent solution is clear but darkens on exposure to light and consequently is stored in a dark bottle. It is almost colorless and does not stain the tissues or linen. The drug is absorbed through the early eschar, reaching its highest level in the blood stream on the second day and receding thereafter until it has disappeared from the blood stream on the sixth day. Blood stream levels range from 2 to 8 mg. per hundred cubic centimeters.

3. Pickrell, K. L. A New Treatment for Burns. *Bull. Johns Hopkins Hosp.* 69: 217-221 (Aug.) 1941.

Sulfadiazine blood levels, measurements of the urinary output and intake, and a study of the urinary sediment for red blood cells and sulfadiazine crystals were done frequently. None of the 32 cases studied exhibited any signs of sulfadiazine toxicity.

were infected and all 4 patients admitted between the second and fourth days were infected. Seven patients had received previous therapy with oils, ointments and grease. Secondary infection was present in 5 of this group, treated previously with home remedies and in 4

32	30	♀	N	1	Hair drier	60/70	None	In hospital condition good			Scalp face abdomen chest arms	45% 3d degree	None

The cases are listed with pertinent data in the table. There were 7 white and 25 Negro patients. The ages ranged from 8 months to 57 years. Six were infants under 2 years of age, 7 were from 2 to 12 years of age and the remaining 19 patients were above 13 years of age. There were 10 burns produced by scalds of hot water, coffee or oil and 22 by flame. Of the 24 admitted during the first twenty-four hours, 2 were infected. Of the 3 admitted in the second twenty-four hours all

of the 25 patients admitted without previous therapy. Of the 9 cases in which infection occurred, 6 entered the hospital after the first twenty-four hours. Of 1 patient with a beta Streptococcus hemolyticus infection of the wound where the eschar had peeled, the infection failed to respond to treatment with sulfanilamide powder, saline wet dressings and azochloramid but cleared promptly following the application of massive wet dressings of the sulfadiazine solution.

Cultures were taken from the wounds on admission, and the organisms usually found were *Staphylococcus albus* and *Escherichia coli*. Of the patients who had previous therapy or were admitted late, subsequent cultures showed beta *Streptococcus hemolyticus* in three, alpha *Streptococcus* in 1 and *Staphylococcus aureus* in the remaining 4.

No patients are included in this analysis in whom less than 10 per cent of the skin area was involved. The area burned varied from 12 to 45 per cent of the body surface. The face was involved in 5, the extremities in 20, and the abdomen, back and chest in 20. All the patients had second and third degree burns. Eight of the 32 patients required skin grafting, usually in twenty-two to forty-four days after the accident. The skin of all the patients was supple.

SUMMARY

1 Treatment employing 2.5 per cent sulfadiazine in 8 per cent triethanolamine was found to be valuable in 30 of 32 patients with second and third degree burns resulting in supple skin without toxic action from the sulfadiazine.

Berkow's method of estimating extensiveness of cutaneous lesions

2 The prompt production of an eschar by spraying and drying alleviates pain and frequent dressings.

3 On the tenth day compresses of 2.5 sulfadiazine in 8 per cent triethanolamine may be used to prevent infection about the separating margin.

4 The solution may be employed without irritation or constriction about the face, mouth, eyes, joints and fingers.

The Thomas Splint in the Last War—The battle of Arras, which took place in April 1917, was about to be fought, and Colonel Gray, being convinced that a great saving in life might be effected in these cases by the use of the Thomas splint as a routine method of fixation, instituted a well organized educational campaign throughout the medical men of the Third Army to achieve this object. This campaign was carried out with the knowledge and approval of General Allenby. A good supply of Thomas splints was distributed to the field ambulances and even further forward, and orderlies were trained to put these on. The result was that cases, instead of arriving at the casualty clearing station almost moribund from shock and exhaustion, came in well enough to stand immediate operation, and the death rate in the clearing station of one army actually fell from nearly 50 per cent in 1916 to 15.6 per cent in 1917—Wade, Henry. *Emergency Surgery in the Field, from War and the Doctor*, edited by J. M. Mackintosh, M.D., Baltimore, William Wood & Co. 1942.

THE INCUBATION PERIOD IN
EPIDEMIC POLIOMYELITIS

ALBERT E. CASEY, M.D.

BIRMINGHAM, ALA.

Recent reviews of work on poliomyelitis¹ contain no data pertinent to the incubation period of this disease in man. Many persons following Wickmann's² lead attempted to estimate the incubation period from the occurrence of multiple cases in given families. Aycock and Eaton,³ in studies of multiple cases in more than 500 families, demonstrated that simultaneous infection is the rule in familial poliomyelitis and that the shorter intervals are probably due to a variation in the incubation period in simultaneously infected persons. Since the method of transmission of the disease has not been proved for man,⁴ the only feasible method of estimating the incubation period directly is to collect a series of instances in which the initial victim in a neighborhood either visited or was visited by a patient with acute poliomyelitis from some other neighborhood.

In an extensive outbreak in Walker County, Ala., in the summer and fall of 1941, there were 37 instances in which the initial victim in a neighborhood followed a single short visit (less than forty-eight hours) to or from a prior victim of acute poliomyelitis.⁵ The place and date of exposure, with the essential data on the victim and on the prior patient, are presented (table 1). Careful histories were taken at the home of the victim and of the contacted child and at the homes of neighbors, friends, relatives and contacts. In 25 neighborhoods I visited every home. As far as could be ascertained, the single exposure recorded was the only instance of exposure to a prior case, or even the only exposure in the immediate vicinity of an acute case. Each victim lived at least a quarter of a mile from the nearest prior victim, and the average distance by road was 4.5 miles and by airline 2.9 miles from the nearest prior victim. The visits averaged hours in intimate contact, the least being a child's ten minutes. The onset was taken as the day on which the first prodromal symptom appeared.

Of the 37 victims 29 had paralytic (78 per cent) and 8 had abortive attacks with signs and symptoms of the central nervous system, 5 of the paralytic cases were fatal. Of the 29 paralyzed victims 22 (76 per cent) had been exposed to another with paralytic poliomyelitis, 6 had been exposed to a patient with abortive poliomyelitis with signs and symptoms of the central nervous system (stiff neck or back, and the like), 1 had been exposed to a child who had a fever eight days after exposure to a patient with a paralytic attack at the onset of its prodromal period.

From the Department of Pathology and Bacteriology, Louisiana State University School of Medicine.

This work was supported by the National Foundation for Infantile Paralysis and the Alabama and Walker County departments of public health.

The incubation period when plotted from the day of exposure to the onset of the prodromal period (chart 1) varied from five to thirty-five days⁶ and averaged 128 ± 12 days for the 29 paralytic cases and varied from five to fifteen days and averaged 9.5 days for the 8 abortive cases. The lack of a sharp peak in the distribution curve was not due to grouping

afebrile interim before the fever associated with the development of paralysis set in. It is possible that some mothers did not detect this prodromal febrile period and that in other instances such a period did not occur. In the abortive cases the prodromal fever seemed to have been vigorous and to have continued generally without an afebrile interval until the develop-

In fact with other groupings two modes were suggested, one at seven to nine days and another at fourteen to fifteen days. These modes were not due to variation in the severity of the disease but seemed to indicate that in a number of instances a prodromal fever curve of one to three days was followed by an

ment of signs in the central nervous system. Perhaps abortive attacks which did not present noticeable prodromal fevers remained undiagnosed and unnoticed in many instances. (This would not be true, of course, with cases of paralytic involvement, and the differences in the average incubation periods may be more apparent than real.)

Because prodromal symptoms may have gone unrecognized in some instances, the incubation period was

6 The minimum incubation period of three days as previously published was in error and was the interval between the onset of the prodromal period in the 2 cases rather than the period from exposure to onset of prodromal symptoms of the victim.

plotted from exposure to the onset of paralysis (chart 2). This gave a unimodal curve having a mode at the fourteenth day, a median at the sixteen day and a mean of 16.9 days, the individual intervals varied from eight to thirty-six days with a skew to the right (chart 2). The skew to the right was pos-

Chart 1—The incubation period in a series of 29 children paralyzed from epidemic poliomyelitis in Walker County, Ala.

sibly due to delayed recognition of paralysis, as minor forms were sometimes not noted until the child began to walk, and the physician was only then consulted.

From the literature⁷ in the United States 11 additional instances were obtained in which a paralytic victim had either visited or been visited by a prior victim (table 2). The incubation period from exposure to onset of the prodromal period varied from five to seventeen days and averaged 10.1 ± 0.9 days. This was not statistically different from the mean incubation period for the paralytic and abortive cases in the Walker County series. By an ingenious study of modes in familial poliomyelitis Aycock and Eaton⁸ estimated the incubation period to be about fourteen days. This indirect method also suggested a bimodal peak, one at seven days and another at eleven to sixteen days (chart 1³), but the authors interpreted the two peaks as inadequacies in history taking in which families were wont to say seven or fourteen days rather than days in between. This did not seem to be the case in Walker County, as most of the

Chart 2—The period between exposure and onset of paralysis in 29 children affected with epidemic poliomyelitis in Walker County, Ala.

histories were taken when the details were fresh in the minds of the persons interviewed and a particular effort was made to guard against this pitfall.

8 Aycock and Eaton (footnotes 3 and 9).

The incubation period in experimental poliomyelitis is usually as low as four to eight days in rhesus monkeys inoculated with the rhesus-adapted MV Rockefeller virus,⁹ but when the same strain of monkey was inoculated with 40 recently isolated human strains by various portals the incubation period varied from four to sixty-four days, averaging 12.3 ± 1.8 days.¹⁰ This mean incubation period is almost exactly the same as that obtained for man in the 37 instances in Walker County, Ala., namely 12.2 ± 1.1 days. In 9 chimpanzees inoculated with recently isolated human strains the incubation period varied from four to eighteen days.

SUMMARY

The incubation period (calculated from exposure to onset of prodromal period) in 37 instances of epidemic human poliomyelitis varied from five to thirty-five days and averaged 12.2 ± 1.1 days. This is compatible with the incubation period in 11 cases taken from the literature and with the incubation period in the rhesus monkey or chimpanzee inoculated with freshly isolated human strains.

INTRAVENOUS ANESTHESIA

HAROLD F. BISHOP, M.D.

WASHINGTON, D. C.

AND

FRED F. RUDDER, M.D.

ATLANTA, GA.

It is our desire to report some experiences and observations associated with intravenous anesthesia. In 1935 evipal soluble was administered to 200 patients. A year later experiences with pentothal sodium were obtained. During the past four years intravenous anesthesia has been carried out on 1,157 patients; 1,136 received pentothal sodium and 21 received evipal soluble. A conservative attitude has been maintained in regard to the selection of patients suitable for intravenous anesthesia and in regard to the dosages employed. Fatalities and serious complications following this type of anesthesia usually can be ascribed to an injudicious choice of a proper anesthetic or to overdosage.¹

Care should be exercised in the choice of all anesthetics. Particularly with intravenous anesthesia should definite criteria be followed. Despite recognition of certain contraindications, this method of anesthesia has a wide application. No attempt has been made to utilize intravenous anesthesia alone for major surgical procedures. It has been used in combination with topical, spinal and block anesthesia. Except for the purpose of induction, it has not been frequently used with inhalation anesthesia, although such a combination may have merit in many instances.

Indications for intravenous anesthesia have been divided into six main divisions: (1) minor short operative procedures, (2) combination with other types of anesthesia, (3) diagnostic procedures, (4) procedures

utilizing electrical apparatus, (5) eye surgery and (6) control of convulsive states. Minor operations of short duration are frequently emergency procedures for which intravenous anesthesia may be preferred over other types of anesthesia. Anesthesia by the intravenous route affords facility to the surgeon in operations about the head and neck. The removal of drains, the dressing of painful wounds, the changing of casts or other procedures which are frequently performed in the ward or in the patient's bed are admirably suited to this form of anesthesia. When there has been recent ingestion of food, the hazard of vomiting can be minimized by intravenous anesthesia. There are many ways in which intravenous anesthesia can be combined with other methods of anesthesia. It is often advantageous to complement or supplement spinal anesthesia by this means. Especially is this applicable to the control of nausea and wrenching associated with spinal anesthesia. A combination of infiltrative or block

In such instances emphasis must be placed on the choice and utilization of a noncombustible general anesthetic such as intravenous. Particularly is this true when high frequency electrical apparatus is used in intraoral surgery or on carbuncles about the head or on the neck. Surgery on the eye lends itself very satisfactorily to intravenous anesthesia. Here again it is advisable to use a topical agent in addition. The agents used for intravenous anesthesia can be used therapeutically in the control of convulsions associated with general or regional anesthesia, eclampsia or tetanus.

A practice has been followed of restricting the use of intravenous anesthetics when any one of the following situations arise: (1) the patient is under 15 years of age, (2) there are inflammations about the mouth and throat with potential encroachment on the upper respiratory tract, (3) there is reduced vital capacity, (4) advanced liver or kidney disease is present, (5)

shock, hemorrhage or anemia is present, (6) there is severe diabetes mellitus, (7) the operation involves the skin primarily, and (8) the patient is ambulatory. Children will require proportionately larger doses of an intravenous anesthetic agent than adults, owing probably to their increased metabolism and reflex irritability. The response to a given dosage seems to be more variable in a child, and veins are often inaccessible. For these reasons intravenous anesthetics had best be excluded in the younger age group. Infections about the mouth and throat which require drainage present a difficult problem in anesthesia. When such a pathologic condition is present, inhalation anesthesia affords greater control over administration than the intravenous route. Patients with reduced vital capacity from chronic pulmonary disease or cardiac disease may exhibit intolerance to intravenous anesthesia. The explanation for such intolerance may be a low blood oxygen and high carbon dioxide level, as Beecher² has pointed out.

It is often assumed that advanced liver or kidney disease or severe diabetes mellitus is a contraindication to the use of intravenous anesthetics. A mild degree of jaun-

dice has appeared following the administration of evipal soluble, although the extent of liver disease was not determined and the jaundice was transient. Operations dealing with cutaneous tissue such as skin grafting and circumcision require large doses of intravenous agents. It has been felt that other anesthetics might be more applicable for these operations. Intravenous anesthesia cannot be recommended for the ambulatory patient, and that excludes its use in office practice. Intravenous anesthesia should probably be excluded in the states of shock, hemorrhage or severe anemia.

The pieces of equipment essential to performance are minimal. Additional equipment aids materially in the management of patients under intravenous anesthesia. A 20 or 30 cc syringe with a No. 19 or No. 20 gage 1½ inch (37 cm) needle is used. The larger needle is used for anesthetics of long duration. A large nasal tube serves as a satisfactory airway. The activity of

Showing one anesthetist without assistance administering intravenous anesthesia and elevating the patient's jaw. The anesthetist has absolute control over the drug at all times and it may be administered intermittently drop by drop simply by turning the gear wheel.

anesthesia plus intravenous anesthesia may be preferable in certain instances. For those patients who are unusually apprehensive, intravenous anesthesia can be instituted for the purpose of induction in the operating room or before the patient's entrance to the operating room. Frequently it is advisable to combine intravenous anesthesia with cocaine or some other topical agent. Intravenous anesthesia in combined form serves as a means of applying this type of anesthesia to major surgical operations without recourse to large doses. Seldom does a diagnostic procedure require general anesthesia, however in some instances it is necessary. Intravenous anesthesia is preferred for cystoscopy and encephalography. Difficulty is always encountered in providing satisfactory general anesthesia for bronchoscopy and esophagoscopy. Provided it is combined with thorough cocaineization of pharynx and larynx, intravenous anesthesia is probably as good a method as any other. In certain situations some type of electrical apparatus such as x-ray or electrocoagulating equipment may be used as a part of or during the operation.

² Beecher, H. K. and Meyer, C. A. Mechanism of Respiratory Failure Under Barbiturate Anesthesia (Evipal, Pentothal). *J. Clin. Investigation* 20: 549-566 (Sept.) 1941.

the pharyngeal reflex is variable and for this reason a pharyngeal airway is not always tolerated. Tracheal intubation may be advisable under certain conditions. Oxygen apparatus is a necessity. An anesthesia machine, a Boothby-Lovclace-Bulbulian mask or oropharyngeal insufflation of oxygen by nasal catheter serves equally well for oxygen administration. We prefer to introduce oxygen by catheter inserted into the nasal or endotracheal tube. A detachable arm board aids in administration if a vein in the arm is selected. The facility afforded by some type of syringe holder is of definite value. By its use control of airway as well as administration of the anesthetic can be simultaneously carried out by one person without assistance. A two way stopcock or similar device is of value when it is desirable to administer intravenous fluids and the anesthetic through the same needle.

We would like to point out and stress certain points in the management of intravenous anesthesia. Adequate premedication is essential and can be obtained preferably by a morphine-scopolamine combination administered one and one-half hours prior to the anesthetic or twenty minutes in advance by vein. We believe that overdosage can be more easily avoided by using the weaker 2.5 per cent solution of pentothal sodium. If evipal soluble is used it is necessary to use a higher concentration. A suitable vein in the arm or leg should be selected as remote from the operative site as possible. Hot packing of the extremities is a valuable procedure if the veins are small or inaccessible. Venipuncture should be performed so that the entire length of the needle down to the hub is contained within the vein. Such puncture insures against dislodgment and subsequent multiple punctures. Cocainization of the pharynx and larynx prior to the insertion of an airway is well worth while. Usually a satisfactory airway can be more easily obtained in a young person than in an elderly patient. In the latter group of patients, particularly if they are without teeth and if the operation is about the face or mouth, it may be advantageous to place a silk suture through the midline of the tongue at the beginning of administration of the anesthetic. By means of a hemostat attached to such suture the base of the tongue can be elevated during the maintenance and recovery periods.

Twenty-two consecutive anesthetics for enucleation of the eye have been reviewed. Four of these were performed under inhalation anesthesia, 7 under block and infiltration and 11 under intravenous pentothal sodium. It was noted that when intravenous anesthesia was used for this operation there was frequently a slowing of the pulse rate during the procedure. Such a reduction of pulse rate did not occur in any of the enucleations performed under other types of anesthetics. Frequently in these 11 cases the pulse rate was maintained at a slower rate than the initial pulse rate. This was unusual in that usually there is a slight or moderate increase in pulse rate under intravenous anesthetics. In 2 cases there was a reading as low as 44 in 1 case a reading of 48 and in 1 case a transient period of bradycardia and arrhythmia just prior to removal of the eyeball.

In studying the records of the anesthetics in these enucleations it became apparent that the development of bradycardia occurred at the time when maximal manipulation was being carried out on the eyeball and surrounding structures. However slowing of the pulse

would continue after the removal of the eyeball. The use of cocaine topically, of procaine introduced as an orbital block or of scopolamine preoperatively did not seem to retard the appearance of bradycardia. The use of the cardiograph is of definite aid in following pulse rates and in detecting abrupt changes in rate and rhythm. Apparently the repeated appearance of bradycardia under intravenous pentothal anesthesia for enucleations is a manifestation of the oculocardiac reflex plus the parasympathetic action of pentothal sodium. This is further evidence of what other observers³ have pointed out—that pentothal sodium accelerates parasympathetic activity. It is this mechanism which is given as the explanation of such phenomena as sneezing, coughing, retching or hiccups, which are all seen infrequently under intravenous barbiturate anesthesia. Such phenomena occur possibly more frequently during eye surgery than during other types of surgery.

The occurrence of such side actions following administration of the barbiturates may be reduced but not completely eliminated by the use of atropine sulfate or scopolamine hydrobromide as premedicants. In 1 case coughing and retching became so severe during induction with pentothal that it was necessary to substitute another form of anesthesia before the operation could be started. Atropine sulfate $\frac{1}{100}$ grain (0.0006 Gm.) was given in this case without effect.

The mechanism of respiratory failure under intravenous barbiturates demands comment. Recently we have observed the creation of apnea lasting for forty-five minutes following administration of 0.7 Gm. of pentothal sodium to a patient suffering from far advanced pulmonary tuberculosis. No response from oxygen under pressure could be elicited. Resuscitation was carried out vigorously with oxygen under positive pressure and carbon dioxide. Apnea may have been prolonged by the use of high oxygen tensions. Respiration was finally initiated following rectal sphincter dilatation. In the light of Beecher's recent explanation⁴ for the occurrence of such phenomena this patient may have had a low blood oxygen and a high carbon dioxide level, and the apnea which was present, might have been maintained by the methods of resuscitation employed.

There has been some question concerning the use of pentothal sodium in a patient who has recently been on sulfur therapy. No known untoward results have followed the combined use of these sulfur containing drugs in our series. It seems probable that no importance need be given to a history of recent sulfur therapy unless, of course anemia is present. It is preferable to use a freshly prepared solution of pentothal sodium. However, we have frequently used a solution which has been allowed to stand for twenty-four to forty-eight hours or more. Apparently no undesirable effects have been produced by the use of such solutions.

SUMMARY

The attitude outlined toward the use of intravenous anesthesia is conservative. It can be considered that there are indications and specific contraindications

Therap.* 63: 215-228 (July) 1938.

4. Beecher H. K.

regarding its application to anesthesia. It is necessary to exercise care in the selection of patients suitable for intravenous anesthesia. Complete equipment is essential in the management of this form of anesthesia. Finally, there is evidence that would indicate that activity of the oculocardiac reflex is exhibited during enucleations of the eye when pentothal sodium is used for anesthesia.

Walter Reed General Hospital

ABSTRACT OF DISCUSSION

DR J ROY FULTON, Commander, U S Navy, Washington, D C. Pentothal sodium and the equipment necessary for its use are available at the present time on board all naval vessels with medical officers. Apparatus for the continuous administration of oxygen under intravenous anesthesia is now available on even our smaller vessels. We have not, however, gone entirely overboard in the use of this method of producing general anesthesia. At our home naval hospitals it is not the anesthetic of choice for routine major surgery. It is reserved for use only when it is especially indicated. We have found this method of anesthesia most applicable for short and minor surgical procedures especially when the operation does not involve the respiratory passages or when extensive muscular relaxation, particularly abdominal, is not required. We have found the method of particular value as a supplement to spinal anesthesia when the effects of the latter begins to wear off or when annoying nausea or vomiting is present. Local and regional anesthesia, supplemented by intravenous pentothal sodium has given us satisfactory anesthesia for extensive intra-abdominal procedures. It has proved to be an ideal anesthetic for the reduction of fractures and dislocations. The method is particularly well suited for surgical procedures about the head and in transurethral and cystoscopic procedures. Pentothal sodium is our anesthetic of choice in the treatment of fresh burns, especially those contaminated by grease or fuel oil. Aboard a combatant ship pentothal sodium anesthesia, because of the rapidity of the induction and the emergence from anesthesia, ease of administration and nonexplosive qualities, has become the anesthetic of choice. During a lull following a naval engagement, the medical officers are being confronted with a large number of seriously injured persons. In their treatment all measures which are both effective and time saving are of utmost value. Although shock is listed as a contraindication to the intravenous use of the quick acting barbiturates our experience has been the same as that of Jarman who stated as a result of his war experience, that pentothal anesthesia does not accentuate the condition of the 'poor risk' patient. As far as I know, there were no deaths under pentothal anesthesia at the naval hospital at Pearl Harbor. I recently returned from a flight to England where I had the opportunity to visit British hospitals and Royal Air Force burn centers. The impression gathered during this short visit was that, although pentothal was being used in some hospitals for prolonged operations, nitrous oxide ether is still the most popular anesthetic for routine major surgery. Pentothal appeared to be the favorite anesthetic for minor cases, for the treatment of burns when an anesthetic was necessary, and for the treatment of compound fractures and wounds of the soft parts in the casualty clearing stations.

DR ROBERT A HINGSON, Staten Island, N Y. I agree largely with what Bishop and Rudder said. Sodium pentothal is a much safer intravenous anesthetic than evipal and we are using it almost exclusively for intravenous anesthesia. In 300 cases at the Marine Hospital, Stapleton, N Y, we had two deaths from evipal. In 1,750 anesthetics with sodium pentothal we have had no serious complications. Several other men in our service had training at the Mayo Clinic and together we have given 4,000 intravenous anesthetics with pentothal since Jan 1, 1940 without a death. We have kept 1 patient under anesthesia for six and one-half hours using 65 Gm of the anesthetic without complications. We have used it for several children without difficulty. The margin of safety here is not as wide as the patients require closer supervision. Intravenous

morphine preoperatively and during the anesthesia reduces the amount of pentothal required. I accept the authors' other restrictions on the use of pentothal except in cases of inflammation about the mouth and throat with encroachment on the upper respiratory tract. Any anesthetic under these conditions is dangerous, but intravenous sodium pentothal supplemented by 100 per cent oxygen through the endotracheal tube is probably the safest of the general anesthetics. The intubation is performed after a 2 per cent pontocaine gargle to obtund the pharyngeal reflexes. Because of the low blood oxygen and high carbon dioxide I feel that a local nerve block anesthetic should be done when practical. If the desired location for the block makes this impracticable because of the infection, I prefer intravenous sodium pentothal with 100 per cent oxygen. There are insufficient trained physician anesthetists in our hospitals, and we have therefore been giving a course in anesthesia to nurses and they have gone on to other Public Health Service hospitals as anesthetists. After six months' training under careful supervision, these nurses make competent anesthetists. During the last months we have been training pharmacist mates in the Coast Guard to administer intravenous anesthesia. Many of these men are premedical students, graduate pharmacists or young men who have had previous hospital or technical scientific training. We have sent out eighteen of these men on the Coast Guard cutters and small craft which operate in our submarine and weather patrol and in the island bases off continental America. These cutters are sometimes away from adequate hospital facilities for months and a single doctor and a pharmacist mate look after the medical needs of two hundred men. We spend three months training these pharmacist mates in the principles of operating room technique, blood transfusion and intravenous and drop ether anesthesia. We believe the annals of wartime surgery will add a new chapter on the increasing usefulness of intravenous anesthesia.

DR FRED T RUDDER, Atlanta, Ga. In the past four years about 10,000 pentothal sodium anesthetics have been given in Atlanta hospitals. A majority of these were given for major surgical procedures. Some lasted for one or two hours or more. There have been no fatalities. From the standpoint of a general surgeon, the relaxation and safety accorded the patient from this type of anesthesia have been satisfactory. I feel that the good results obtained are due to the strict adherence to the principle of slow, intermittent administration of the drug as advocated by Dr Lundy. I also feel that the continuous use of oxygen, 3 to 4 liters per minute throughout the operation, has been of definite value. That one anesthetist without assistance might administer the drug in drop by drop doses and give oxygen at the same time, I have developed a syringe holder with a rack and pinion gear attachment that allows one anesthetist absolute control over the drug at all times. Clotting of blood in the needle cannot occur because the movable arm of the holder will not allow the back flow from the vein into the lumen of the needle. This syringe holder has simplified the administration of the drug in operative procedures of long duration.

Science and the War—Will the present world war have equally advantageous effects on the advancement of science? Or will an exhausted and disillusioned world ascribe its woes to science and turn from it to philosophy or some mystic religion for happiness? It is hazardous to make predictions, for human beings in distress reach strange conclusions and do strange things. However, it is certain that as yet there has been no decrease in scientific activity. On the contrary, science was never before so highly respected or so eagerly cultivated. Although the primary purpose of much of current scientific work is destruction, a considerable fraction of it will have more important applications after peace returns. It would be easy to dream of an abundance of the things that are now scarce of better substitutes for these things, of better houses, or more of everything that men want and that science and technology can produce.—Moulton, F R. Science and Technology, *Am J Advance Science Bull*, July 1942, p 33.

PANEL DISCUSSION ON PEPTIC ULCER

The first five papers in this discussion, by B R Kirklin and William C MacCarty Jr, Rochester, Minn., J Earl Thomas, Philadelphia, Samuel Morrison and Maurice Feldman, Baltimore Harry Shay, Jacob Gershon-Cohen, Samuel S Fels and Herman Siplet, Philadelphia, and Asher Winkelstein Albert Cornell and Franklin Hollander, New York were published in The Journal last week The following five papers and the discussion from the floor, published in this issue of The Journal complete the panel discussion on peptic ulcer

BLEEDING PEPTIC ULCERS

ONE HUNDRED AND FIFTY-ONE FATALITIES

JOHN M BLACKFORD, MD

AND

HORACE E ALLEN MD

SEATTLE

The Bureau of Vital Statistics of the City of Seattle (U S Census 1940 368 302 population) has death certificates showing that 151 persons during the past seven years (1935-1941 inclusive) have died as the immediate result of hemorrhage from peptic ulcer This study is based on all such cases recorded in the cross index of the Bureau of Vital Statistics plus some additions and minus some exclusions made after a review of each of the 33,987 death certificates recorded during these seven years Each case recorded as death due to bleeding from peptic ulcer has been traced back to the hospital record, to the physician in charge or to the family of the deceased in order to get all possible information The records have usually been found unsatisfactory because the emergency of a fatal hemorrhage makes history taking difficult and the patient cannot later fill in any deficiencies in the history Yet the physician in charge should always know that the patient died from gastric bleeding and could hardly fail to note this fact on the death certificate

ACCURACY OF DIAGNOSIS

Postmortem study was made in more than half (76) of the cases, thanks to the activity of autopsy services in Seattle hospitals Clinical evidence only has been the basis of the diagnosis in 75 cases

We have attempted to include only deaths due directly to hemorrhage from peptic ulcer We have therefore excluded all cases of bleeding from (1) carcinoma of the stomach or esophagus, (2) esophageal varices, (3) hemorrhagic gastritis, (4) hemorrhagic diatheses, (5) sudden fatal gastric hemorrhage, which is the only evidence of peptic ulcer, and (6) gastrojejunal or marginal ulcerations We believe that the clinical diagnosis of death from bleeding ulcer is at least 90 per cent correct in the cases not coming to autopsy and that the diagnosis in the group of cases coming to autopsy must approximate 100 per cent correct, or that the diagnosis of death due to bleeding from peptic ulcer is correct in about 95 per cent of the 151 cases studied

Our previously reported cases are included in this study, and a comparison with the formed studies shows

From the Mason Clinic
Dr Bryan Newson of the Division of Vital Statistics of Seattle gave indispensable advice and allowed the use of the facilities and records of his bureau

Read in the Panel Discussion on Ulcer before the Section on Gastro-Enterology and Proctology at the Ninety Third Annual Session of the American Medical Association Atlantic City N J June 11 1942

no significant variations Each year the number of fatalities in Seattle has ranged between 17 and 27 cases, and, consistently, one half of the cases have come to autopsy (chart 1) In this series thirteen operations were undertaken as emergency attempts to save life, but only two of these operations were done within forty-eight hours after the beginning of the hemorrhage

LOCATION OF ULCERS

Seventy-six autopsy reports record the location of the ulcer as gastric in 46 cases and duodenal in 26 cases, in 4 cases the location is not recorded Thus two thirds of the recorded locations are gastric This is in startling contrast to the well known clinical predominance of duodenal ulcer as from four to ten times more common than gastric ulcer

AGE AND SEX

Thirty-one women and 120 men died from bleeding ulcer, showing that one fifth were women (chart 2)

The age incidence was interesting Only one death occurred in the twenties, one in the thirties and six between the ages of 40 and 45 years, a total of eight deaths among patients under 45 After the age of 45, there is a great increase in the number of deaths Nearly two thirds of all bleeding ulcer deaths occur in the fifties and sixties, whereas the seventies show more deaths from all causes¹ than any other decade Most bleeding ulcer deaths occur in the fifties while the greatest number of deaths from all causes occur in the seventies

STUDY OF CLINICAL RECORDS

Every effort has been made to obtain all available information, and it is much to be regretted that such information is sometimes very incomplete, nevertheless we have attempted to get as accurately as possible, and from all sources available, some idea as to the severity of ulcer symptoms in each case, whether serious symptoms were present immediately preceding the fatal hemorrhage and whether there had been a former hemorrhage

It is a striking fact that in the majority of cases there was not a history of extremely severe ulcer In a remarkable number there had been really mild ulcer symptoms, many patients did not even know that they had peptic ulcer One third of the fatal hemorrhages occurred during a period of quiescence of any ulcer symptoms (table 1)

In only 35 cases (23 per cent) was there a history of former hemorrhage, more than three fourths of all fatalities occurred following the first hemorrhage Studies of peptic ulcer hemorrhage are usually based on records of patients who have recovered from the first hemorrhage, and most reports are therefore greatly concerned with only some 23 per cent of the total

1 The number of deaths by decades for 1941 is estimated

number of fatalities from ulcer hemorrhage for the whole population. Surgical discussions usually have emphasized the dangers of recurring hemorrhages, yet, if all deaths are considered, such discussions concern less than one fourth of all deaths from peptic ulcer hemorrhage.

Chart 1—Fatalities from peptic ulcer hemorrhage and deaths from all causes in Seattle 1935 to 1941 inclusive

PLACE OF DEATH

Most of the deaths occurred in hospitals and almost all deaths studied in the literature are hospital deaths, yet in Seattle 34 (23 per cent) of the deaths occurred at home (table 2). Of these 34 patients 19 were past 70 years of age.

In our total series there were 38 deaths of patients past the age of 70 and 19, or exactly half this number, died at home. Families evidently do not rush grandpa or grandma to the hospital for an exsanguinating gastric hemorrhage, and the mortality at advanced age is undoubtedly very high.

GENERAL OBSERVATIONS

In our clinical experience bleeding from peptic ulcer is recorded in the history of 20 to 25 per cent of all cases of peptic ulcer and 60 per cent of the first hemorrhages occur when the patient is under the age of 45, no fatality from peptic ulcer hemorrhage has occurred in

Chart 2—Age and sex distribution of one hundred and fifty-one fatalities from peptic ulcer hemorrhage

this younger group. It may be safely stated that fatalities in patients under 45 are rare, whether the patient receives treatment or not, and that in patients under 40 years of age fatalities are almost unknown. After the age of 45, the number of fatalities from hemorrhage increases rapidly. Almost two thirds of all the deaths in this series occurred between the ages of 50 and 70 years, and two thirds of these were from bleeding

gastric ulcer. Three fourths of all the fatalities occurred following the first hemorrhage. Autopsy study has almost always shown a large arteriosclerotic, eroded artery in the base of the ulcer, most of the postmortem reports emphasize extensive generalized arteriosclerosis.

Simultaneous acute perforations and massive hemorrhage are rare, 3 such instances have been found in this study, and death was considered due to exsanguination rather than to peritonitis.

These 151 cases have been recorded in the vital statistics of the city of Seattle. It should be mentioned that "metropolitan Seattle" in 1940 had a U. S. Census of 452,639 and that this is the population which is tributary to Seattle hospitals. The city has averaged more than twenty-two deaths each year from bleeding peptic ulcer. These patients might have been seen by any of our more than seven hundred doctors. It is not surprising that many busy practitioners have never seen a patient die from peptic ulcer hemorrhage and that busy gastroenterologists have seen relatively few.

Statistics regarding the life saving success of treatments for peptic ulcer hemorrhage have usually not separated the cases into age groups but have reported percentages based on all cases in all age groups.

We are confident that if an attempt is made to segregate the group of older patients with exsanguinating hemorrhages, such a group will have a mortality rate of approximately 30 per cent. If we exclude this group from mortality figures, we exclude those who die at home and those who die promptly before treatment can be administered or considered effective, thus excluding 82 per cent of all fatalities and we have left a group whose mortality rate approaches the vanishing point.

SUMMARY

A study of all fatalities from bleeding peptic ulcer during seven years in Seattle has shown (1) that 95 per cent occurred in patients past 45 years of age, (2) that 77 per cent occurred following the first hemorrhage, (3) that 22 per cent occurred at home, (4) that 21 per cent occurred in women, and (5) that in the 76 autopsies performed the fatal hemorrhage arose from a gastric ulcer in two thirds (64 per cent) and from a duodenal ulcer in one third (36 per cent).

MEDICAL AND SURGICAL TREATMENT
OF HEMORRHAGE FROM
PEPTIC ULCER

A CRITICAL EVALUATION OF THE FACTOR OF AGE

JACOB MEYER, M.D.

HERTHA KOHN SORTER, M.D.
ANDHEINRICH NECHELES, M.D., Ph.D.
CHICAGO

The treatment of bleeding peptic ulcer is still a controversial subject. Surgical as well as medical authorities have recognized the importance and value of conservative measures.

The most important clinical observations that have led both surgical and medical authorities to follow conservative procedures are as follows. In persons under 45 years of age death seldom occurs from the first hemorrhage. The risk to life from hemorrhage in younger patients is a fraction of 1 per cent and the risk does not exceed 1 per cent if massive exsanguinating hemorrhages are considered. No surgical procedure carries a risk of less than 1 per cent. Persons under 45 may have many episodes of severe hemorrhage and recover. The medical treatment of bleeding ulcer when all ages are considered gives a lower mortality than surgical treatment.¹

In contrast to these experiences there is a group of physicians who believe that the treatment should be surgical. The chief of this school is Finsterer, who advocates immediate (twenty-four to forty-eight hours) resection in all cases of massive hemorrhage and reports a mortality of 4.2 per cent. There are others who advocate early operation such as ligation of the bleeding ulcer area, to be followed later by a suitable operation.

The arguments of this group are as follows. The operative mortality is low if operation is performed early and if the patient is not operated on in a moribund state. In patients past 45 years of age death may occur during the first hemorrhage. In the aged patient an eroded arteriosclerotic blood vessel which fails to contract may be the cause of death while an operation and ligation of the bleeding vessel gives the only hope of saving the patient in such instances. Perforation often accompanies hemorrhage and is overlooked, thus being the cause for death.

These observations have led physicians and surgeons to regard the age of the patient as the important factor in determining the type of treatment in bleeding peptic ulcer. Our object in this paper is to evaluate the age factor and to compare the results of medical and surgical treatment in similar age groups.

PRESENT REPORT

This report is a study of 154 cases of bleeding peptic ulcer admitted to the Michael Reese Hospital during the past ten years and verified by history, physical examination, laboratory tests and x-ray studies. In 54

cases diagnosis could be confirmed by x-ray examination and in 100 by history, physical examination and laboratory studies.

In the study only group 1 of table 1 will be considered.

"Conservative medical management" signifies an accepted form of medical treatment, namely absolute bed rest, administration of morphine, repeated blood transfusions and twenty-four hour starvation followed by small hourly feedings of a soft diet. The surgical treatment was subtotal gastric resection by a modified Polya technic, as described previously by our group.³ Resections were performed from a few days to several weeks after the occurrence of hemorrhage.

RESULTS OF CONSERVATIVE MEDICAL TREATMENT

Of 111 patients with bleeding peptic ulcer treated medically 8 died, a mortality of 7.2 per cent. In this group of 111 patients 71 were past 45 years of age. All 8 deaths occurred in this group, so that on the basis

21.44	25	0	0	15	0

of age alone the mortality would be 11.3 per cent. On the basis of severity of hemorrhage⁴ and age there were 38 patients between the ages of 45 and 73 who had severe hemorrhage and 8 of these died, the mortality being 21 per cent.

RESULTS OF RESECTION

In this study we are considering only the results of resections in cases of bleeding gastric and duodenal ulcers. Thirty-one patients were operated on; gastric resection was performed on 28, while gastroenterostomy, ileostomy and ligation, and gastrojejunostomy or jejunostomy were performed on 3 other patients. These 3 patients, of whom 2 died, are not considered in this analysis, nor is 1 patient with gastrojejunal ulcer on whom resection was performed and who died.

There were 27 patients with bleeding peptic ulcer regarded as serious who were having sufficient symptoms or complications to warrant resection. An analysis of the histories showed that 17 of these patients had a severe and 10 had a mild hemorrhage. There were 6

deaths among the 27 patients on whom resection was performed, which gives a total mortality rate of 22.2 per cent. Analysis on the basis of age and severity of the hemorrhage shows that 7 patients were in the age

In our study of 111 patients with hemorrhage who were treated conservatively and who lived and were well there were 45 who had their first hemorrhage at the age of 45 or past. In 25 the first hemorrhage was regarded as severe and in 20 as mild. The mortality rate from severe initial hemorrhage in our subjects past 45 was 28 per cent (7 deaths). This is a relatively high mortality rate and is in accord with the studies of Blackford and Williams, 30 per cent.¹ On the other hand, 2 of the 3 patients past 45 years of age who died after resection had the first severe hemorrhage at this age or past.

It is important, therefore, to analyze the causes of death of patients treated by conservative medical measures and by resection in the age group of 45 years and over. Such an analysis is made in tables 4 and 5. Of the 8 deaths of patients treated medically, all were men 45 years or older, and the hemorrhage in 7 of the cases was the first one and all were regarded as severe. The autopsy in 3 of these revealed in 1 a perforating ulcer and peritonitis, in another an erosion of a branch of

mild hemorrhage on whom resection was performed and their age distribution are included in table 3.

These data are quite significant because they indicate a rather high mortality rate among the patients with severe hemorrhage past 45 years of age (42.9 per cent), as well as under 45 years of age (30 per cent), in sharp contrast to the results in similar age groups under conservative medical treatment (21 per cent mortality in the older, and no mortality in the younger group). It is particularly noteworthy that in the group of patients under 45 years of age treated medically the mortality was nil.

Does a severe initial hemorrhage in a person past the age of 45 indicate a grave prognosis? Does a hemorrhage at this age or past this age justify an operative procedure? Seven of our patients past 45 years of age under conservative medical therapy died from the first hemorrhage. Allen⁵ and Blackford and Cole¹ state that massive hemorrhages in older patients cause a mortality rate approximating 30 per cent. Allen⁵ reported 60 per cent fatalities following the first hemorrhage. Blackford and Williams¹ state that 78 per cent of all deaths occur following the first hemorrhage.

the gastric artery, and in the third an ulcer penetrating into the pancreas with erosion of three blood vessels and aortic insufficiency. It may be inferred that operative intervention such as resection might have saved the lives of these 3 patients.

On the other hand analysis of the patients who had resection performed and died reveals that of 3 patients past 45 1 died of bronchopneumonia and ileus 1 of peritonitis and 1 of bronchopneumonia, esophagitis and necrotizing gastritis. The causes of death of 3 patients under 45 years of age were peritonitis, exsanguination and bronchopneumonia. Therefore, it may be concluded that the errors of judgment or diagnosis in the two forms of treatment were approximately the same. At least in this small series it is not possible to say that treatment by resection offers an improvement on the mortality rate in the advanced age group with severe hemorrhage.

It is significant that many patients past 45 showed evidence of coronary sclerosis, arteriosclerosis, hypertension or other complicating disease. These observations are generally regarded as a contraindication to operation, and postoperative death is generally attributed to these associated conditions. There are undoubt-

5 Allen A W. Surgery 2:713-731 (Nov.) 1937.

edly instances in which these associated conditions may be a cause of death, but we have seen a number of older patients who were operated on for gallstones, prostatic tumor or the like and who were presumed to have died from an acute bleeding peptic ulcer. (These studies are being reported.) We stress this point because we feel that, even though our statistics favor the medical treatment of the severe bleeding ulcer, there is need for an awareness of the value of immediate surgical care in a number of cases and that neither the age nor the associated condition (within certain limitations) should deter the surgeon from operation.

DO PATIENTS PAST FORTY-FIVE WHO SURVIVE
THE FIRST HEMORRHAGE DIE OF A
SUBSEQUENT HEMORRHAGE?

It is apparent from our analysis that approximately 70 per cent of patients who have their first severe hemorrhage at 45 or later survive. The question arises: What is the course that these patients pursue? Do they have a hemorrhage later and die? Such information would be of value in determining the type of treatment which would yield the best end result.

a severe hemorrhage two to three years later and survived. It would appear then that it is both difficult and hazardous to predict the nature of subsequent hemorrhage if the patient past 45 survives the first hemorrhage. Further studies of this group are needed to answer this question definitely.

A severe hemorrhage in a patient with a chronic duodenal ulcer of many years' duration is generally regarded as an indication for surgery. This has been our practice, because in such instances an erosion of a rather large blood vessel is usually the cause of the hemorrhage. It appears, however, that there have been a number of patients who have had repeated severe hemorrhages and who have continued to live and do well on medical treatment. We found a total of 28 patients past 45 years of age who had more than one hemorrhage before and after the age of 45. Three had three previous, 10 had several and 1 patient aged 57 had seven previous hemorrhages. Twenty-four of these patients were 50 years of age or older and 8 of these were 60 or older. The duration of symptoms of these patients ranged from three to twenty years.

TABLE 5—Analysis of Deaths (Severe Hemorrhage) Resection (All Males)

was not stated. Two of these patients with severe initial hemorrhage had one subsequent severe hemorrhage and continued to live, and of 4 patients who previously had what was termed mild hemorrhage all 4 had

SUMMARY AND CONCLUSIONS

Our studies revealed that the conservative medical treatment of bleeding peptic ulcer resulted in a mortality rate of 7.2 per cent, irrespective of the age of the patient and the severity of the hemorrhage. Among persons 45 years of age and older with severe hemorrhage the mortality rate was 21 per cent and among those with initial severe hemorrhage the mortality rate was 28 per cent, while among the patients under 45 with severe hemorrhage there was no mortality.

In striking contrast, the patients with bleeding peptic ulcer treated by resection had a total mortality rate of 22.2 per cent. Among patients past 45 with severe hemorrhage the mortality rate was 42.8 per cent and among those under 45 who had resections the mortality rate was 30 per cent.

Our studies should not give the impression that we oppose surgery in the treatment of bleeding peptic ulcer. Rather we point out that among those patients treated medically surgery might have saved the lives of at least 3 patients. We agree with the observations of others that the surgeon should be available for severe bleeding ulcers in patients past 45 but that the indication for surgical intervention should be tempered by all the clin-

ical factors rather than by the age of the patient only. These factors are the severity of the hemorrhage, the response to blood transfusions and the general condition of the patient. We emphasize particularly that, according to our data, among patients under 45 years of age operation is best avoided, since conservative medical treatment was attended with no mortality. We recognize the importance of cooperation between the surgeon and the internist in the care of these patients. Surgical treatment—resection of bleeding peptic ulcer—has not in our series shown an improvement in the mortality rate as compared with conservative medical treatment. One must recognize that in the conservative medical treatment there will be instances in which, had operation been performed, the life of a patient might have been saved. It appears equally true, however, that considering the errors of diagnosis there are, to say the least, as many patients who might have died following surgery. Our observations indicate that many patients past 45 have repeated hemorrhages from peptic ulcer and continue to live on medical treatment for many years.

Such associated conditions as hypertension, coronary sclerosis and arteriosclerosis should not deter the internist or the surgeon from recommending operation in selected cases of severe bleeding peptic ulcer.

55 East Washington Street

THE SELECTION OF OPERATION FOR PATIENTS WITH GASTRIC AND DUODENAL ULCER

J. WILLIAM HINTON, M.D.

AND

REYNOLD E. CHURCH, M.D.

NEW YORK

The first consideration when discussing operations on patients with gastric and duodenal ulcer is the fact that an ulcer, whether gastric or duodenal, constitutes a medical problem, and surgery is resorted to only for the complications resulting from an ulcer. The emergency surgery for the acute perforation, or occasionally for massive hemorrhage, and the elective surgery for the chronic ulcer should not comprise over 20 per cent of the patients treated.

In this presentation, the conclusions have been drawn from the combined medical and surgical ulcer clinic, which was established in the Fourth Division at Bellevue Hospital in January 1928. The clinic has always been manned by internists and surgeons, and it has been our feeling at the hospital at all times that medical management was the treatment of choice in all uncomplicated ulcers and that surgery should be resorted to only in the complicated cases. One should realize that the patients treated are from a municipal hospital and would come nearer representing the population of the country at large than patients from a higher economic status. In this discussion private patients are not included nor are patients from other hospitals, since this is an attempt to evaluate the cycle of the ulcer patients over years of observation. During the past fourteen years, or from 1928 to 1941 inclusive, we

have had occasion to treat 1,256 patients suffering from gastric or duodenal ulcer. These patients have made 24,324 visits, or an average of 19 visits a patient, and we have had occasion to be present 95 per cent of the time when the clinic was conducted. We are therefore speaking from personal observation of the patients and not from a statistical evaluation of figures taken from a record room alone.

Of the patients, 89 per cent had duodenal and 11 per cent had gastric ulcer. They averaged 35.1 years of age, 88 per cent were males and 12 per cent were females. When these patients were registered there were 263 who had had previous operations performed, 155 for acute perforations, 20 for massive hemorrhage and 88 for chronic ulcers. That leaves 993 patients with unoperated ulcers registered in our clinic. Of this number, 493 had received no previous medical treatment while 500 had received some form of medical treatment or advice. The duration of these patients' symptoms averaged four and one-half years. Of the 993 patients not operated on during the fourteen year period 66 per cent had been improved by medical management, 24 per cent were not improved and 10 per cent have been followed three months or less, which is insufficient time to evaluate the progress of their disease. We have advised 140 patients out of this group to be operated on, which is 14 per cent of the total number of patients who had not been operated on.

From observations in our clinic the prime misunderstanding as to the surgical indications and contraindications hinges around one fundamental point, namely the duration of symptoms before medical advice is sought. Obviously a patient seen in the first few months of the disease offers a simpler problem for medical management than does one seen a number of years after onset of the disease. We wish to reiterate, our patients had suffered from the disease for four and one-half years before seeking treatment.

We have been thoroughly convinced after following the cases in our clinic that medical management in the uncomplicated ulcers gives better results than does surgical management in similar cases. There comes a time in the life cycle of certain patients with ulcer when medical management ceases to be effectual in controlling their symptoms, and this event occurs when the ulcer has become adherent to an adjacent viscus, so that one is not dealing with a simple ulcer but one which has perforated the wall of the stomach or duodenum and the floor of the ulcer is formed by an adjacent viscus. The organ most frequently involved by this process is the pancreas, but we have seen both a gastric and a duodenal ulcer in patients who have not been operated on perforate through the wall of the organ and into the transverse colon. Likewise, we have seen an ulcer perforate from the duodenum into the fundus of the gallbladder and from the duodenum into the common duct.

Therefore it is well for the internist to realize that in cases in which there has been thorough medical treatment and the ulcer has failed to respond surgery must be definitely advised so as to reduce to a minimum the complications enumerated. We have recommended operations to only 14 per cent of the total number of patients not operated on who have been encountered in a municipal hospital. It would seem fair to assume that surgery is not indicated in more than 20 per cent of the total number of these patients under observation.

There are two complications which are most likely to occur in unoperated ulcers, namely acute perforations and massive hemorrhage. Of the total number of patients registered in our clinic, 1,256, there were 155 with acute perforations, 84 with massive hemorrhages and 93 with mild hemorrhage. Surgery had been advised in only 39 of the 84 cases of massive hemorrhage and 36 of the 93 cases of mild hemorrhage.

It is necessary for patients to remain under medical treatment for long periods, and our patients have averaged two years under active medical treatment. As previously stated, 10 per cent of the 993 cases have been followed three months or less and have been excluded from evaluation owing to the limited period of observation.

Only the pathologic process encountered by the senior author is reported, since this has a most significant bearing on the type of operation that should be performed. The five year period from 1928 to 1932 was the time when gastroenterostomy was the operation of choice. It was our feeling that in properly selected patients one encountered good results from this method of surgical treatment. We have evaluated our surgical results on three different occasions. In 1934 we reported 96 gastroenterostomies followed on an average of 4.2 years and in that report 16.7 per cent of the ulcers encountered were gastrojejunal ulcers. At the same time only 3.7 per cent of the patients were cured, 12 per cent were benefited and 51 per cent were unimproved. A number of the operations in this series antedated the starting of our clinic in 1928 and the cases were merely followed in the clinic. In 1940 we reported on 106 gastroenterostomies followed for 7.1 years and found at that time that only 24.5 per cent of the patients were cured. At this time the diagnosis was gastrojejunal ulcer in 18.8 per cent and in 5.6 per cent the roentgen findings and symptoms suggested a gastrojejunal ulcer which made a total of 24.4 per cent of the cases in which there apparently was suffering from gastrojejunal ulcer. One would naturally ask why we encountered such a high percentage of failures and it is our feeling that this is directly related to the pathologic process which was encountered at the time of the original operation.

We are convinced that gastroenterostomies done on uncomplicated ulcers will give a far higher percentage of good results than those which we have reported because one would be dealing with an ulcer in the early stages which has not penetrated the wall and involved the adjacent viscus. Therefore the problem is merely healing of the primary ulcer and if one is fortunate to avoid a gastrojejunal ulcer the results will be quite satisfactory. But, likewise, excellent results are obtained in this type of case from medical management and surgery is not indicated.

The discussion of the surgical management of an ulcer rests on the pathologic process encountered and it is difficult to evaluate the pathologic process in the adjacent viscus unless a subtotal resection has been performed. During the five year period from 1928 to 1932 we had occasion to do twenty-nine gastroenterostomies for duodenal ulcers. The pathologic

process encountered in these cases was described as being an anterior duodenal ulcer in 14 instances, posterior in 13 and both anterior and posterior in 2. The age of the patient and duration of the symptoms were the same for the gastroenterostomy series and the subtotal series namely 37.1 years for the former and 37.1 years for the latter, and the symptoms were present for 5.4 years in the former and 5.3 years in the latter. One would expect to encounter similar pathologic processes in the two groups but the subtotal findings did not confirm this.

Evaluation of the 102 subtotal resections which had been done from 1933 to 1941 inclusive revealed that 27 patients had gastric ulcers and 75 had duodenal ulcers, or 27 per cent of total operations were for gastric ulcers. Patients referred for operation constituted 14 per cent of all who had not been operated on. The point is worth emphasizing as it is our feeling that an uncomplicated gastric ulcer responds satisfactorily to medical management and that the fear of malignant degeneration in gastric ulcer has been greatly over-emphasized in an evaluation of the clinical course of the gastric ulcer under medical management over a period of years.

A clinician should not enter into controversy as to the histologic diagnosis of a gastric ulcer versus a gastric malignant growth as it is well known that different schools of pathologists differ widely as to what constitutes malignant degeneration in the cells. A patient suffering from a gastric lesion whose roentgen examination, clinical course and gastroscopic findings suggest that the lesion may be malignant should be operated on immediately and that has been our policy. But in the case of a gastric lesion in which there has been no difficulty in making the diagnosis between an ulcer and a carcinoma the patient is handled by medical management and with fourteen years of clinical experience we have no reason to regret.

As the ulcer problem to a great extent is the problem of duodenal ulcer which in our series constituted 89 per cent of the total ulcers encountered the majority of ulcers which come to operation will be duodenal lesions. It is in this group of patients that so much misunderstanding still exists and after the abdomen has been opened it is difficult if not impossible for one to be sure whether the pathologic process encountered represents an anterior duodenal ulcer, a posterior wall ulcer or an ulcer on both anterior and posterior walls. In a series of 75 patients with duodenal ulcers coming to subtotal resections there were 60 or 80 per cent of the total number with posterior wall ulcers, and all these patients had a definite associated chronic pancreatitis and usually this was of an extensive degree. In 10 instances or 13 per cent there was both an anterior and a posterior wall ulcer and in 5 cases, or 7 per cent of the total there was a single anterior wall ulcer. In all cases of the double ulcers there was likewise an associated pancreatitis. These figures would tend to prove that the anterior ulcer, if treated medically will respond satisfactorily to medical management and will rarely come to surgical intervention unless for acute perforation and very occasionally for massive hemorrhage.

In the case of duodenal lesion it has been our policy to recognize only one true indication for recommending surgery in the chronic ulcer. That is uncontrollable

ical factors rather than by the age of the patient only. These factors are the severity of the hemorrhage, the response to blood transfusions and the general condition of the patient. We emphasize particularly that, according to our data, among patients under 45 years of age operation is best avoided, since conservative medical treatment was attended with no mortality. We recognize the importance of cooperation between the surgeon and the internist in the care of these patients. Surgical treatment—resection of bleeding peptic ulcer—has not in our series shown an improvement in the mortality rate as compared with conservative medical treatment. One must recognize that in the conservative medical treatment there will be instances in which, had operation been performed, the life of a patient might have been saved. It appears equally true, however, that considering the errors of diagnosis there are, to say the least, as many patients who might have died following surgery. Our observations indicate that many patients past 45 have repeated hemorrhages from peptic ulcer and continue to live on medical treatment for many years.

Such associated conditions as hypertension, coronary sclerosis and arteriosclerosis should not deter the internist or the surgeon from recommending operation in selected cases of severe bleeding peptic ulcer.

THE SELECTION OF OPERATION FOR PATIENTS WITH GASTRIC AND DUODENAL ULCER

J. WILLIAM HINTON, M.D.

AND

REYNOLD E. CHURCH, M.D.

NEW YORK

The first consideration when discussing operations on patients with gastric and duodenal ulcer is the fact that an ulcer, whether gastric or duodenal, constitutes a medical problem, and surgery is resorted to only for the complications resulting from an ulcer. The emergency surgery for the acute perforation, or occasionally for massive hemorrhage, and the elective surgery for the chronic ulcer should not comprise over 20 per cent of the patients treated.

In this presentation, the conclusions have been drawn from the combined medical and surgical ulcer clinic, which was established in the Fourth Division at Bellevue Hospital in January 1928. The clinic has always been manned by internists and surgeons, and it has been our feeling at the hospital at all times that medical management was the treatment of choice in all uncomplicated ulcers and that surgery should be resorted to only in the complicated cases. One should realize that the patients treated are from a municipal hospital and would come nearer representing the population of the country at large than patients from a higher economic status. In this discussion private patients are not included nor are patients from other hospitals, since this is an attempt to evaluate the cycle of the ulcer patients over years of observation. During the past fourteen years, or from 1928 to 1941 inclusive, we

have had occasion to treat 1,256 patients suffering from gastric or duodenal ulcer. These patients have made 24,324 visits, or an average of 19 visits a patient, and we have had occasion to be present 95 per cent of the time when the clinic was conducted. We are therefore speaking from personal observation of the patients and not from a statistical evaluation of figures taken from a record room alone.

Of the patients, 89 per cent had duodenal and 11 per cent had gastric ulcer. They averaged 35.1 years of age, 88 per cent were males and 12 per cent were females. When these patients were registered there were 263 who had had previous operations performed, 155 for acute perforations, 20 for massive hemorrhage and 88 for chronic ulcers. That leaves 993 patients with unoperated ulcers registered in our clinic. Of this number, 493 had received no previous medical treatment while 500 had received some form of medical treatment or advice. The duration of these patients' symptoms averaged four and one-half years. Of the 993 patients not operated on during the fourteen year period 66 per cent had been improved by medical management, 24 per cent were not improved and 10 per cent have been followed three months or less, which is insufficient time to evaluate the progress of their disease. We have advised 140 patients out of this group to be operated on, which is 14 per cent of the total number of patients who had not been operated on.

From observations in our clinic the prime misunderstanding as to the surgical indications and contraindications hinges around one fundamental point, namely the duration of symptoms before medical advice is sought. Obviously a patient seen in the first few months of the disease offers a simpler problem for medical management than does one seen a number of years after onset of the disease. We wish to reiterate, our patients had suffered from the disease for four and one-half years before seeking treatment.

We have been thoroughly convinced after following the cases in our clinic that medical management in the uncomplicated ulcers gives better results than does surgical management in similar cases. There comes a time in the life cycle of certain patients with ulcer when medical management ceases to be effectual in controlling their symptoms, and this event occurs when the ulcer has become adherent to an adjacent viscus, so that one is not dealing with a simple ulcer but one which has perforated the wall of the stomach or duodenum and the floor of the ulcer is formed by an adjacent viscus. The organ most frequently involved by this process is the pancreas, but we have seen both a gastric and a duodenal ulcer in patients who have not been operated on perforate through the wall of the organ and into the transverse colon. Likewise, we have seen an ulcer perforate from the duodenum into the fundus of the gallbladder and from the duodenum into the common duct.

Therefore, it is well for the internist to realize that in cases in which there has been thorough medical treatment and the ulcer has failed to respond surgery must be definitely advised so as to reduce to a minimum the complications enumerated. We have recommended operations to only 14 per cent of the total number of patients not operated on who have been encountered in a municipal hospital. It would seem fair to assume that surgery is not indicated in more than 20 per cent of the total number of these patients under observation.

There are two complications which are most likely to occur in unoperated ulcers, namely acute perforations and massive hemorrhage. Of the total number of patients registered in our clinic, 1,256 there were 155 with acute perforations, 84 with massive hemorrhages and 93 with mild hemorrhage. Surgery had been advised in only 39 of the 84 cases of massive hemorrhage and 36 of the 93 cases of mild hemorrhage.

It is necessary for patients to remain under medical treatment for long periods, and our patients have averaged two years under active medical treatment. As previously stated, 10 per cent of the 993 cases have been followed three months or less and have been excluded from evaluation owing to the limited period of observation.

Only the pathologic process encountered by the senior author is reported, since this has a most significant bearing on the type of operation that should be performed. The five year period from 1928 to 1932 was the time when gastroenterostomy was the operation of choice. It was our feeling that in properly selected patients one encountered good results from this method of surgical treatment. We have evaluated our surgical results on three different occasions. In 1934 we reported 96 gastroenterostomies followed on an average of 4.2 years and in that report 167 per cent of the ulcers encountered were gastrojejunal ulcers. At the same time only 37 per cent of the patients were cured, 12 per cent were benefited and 51 per cent were unimproved. A number of the operations in this series antedated the starting of our clinic in 1928 and the cases were merely followed in the clinic. In 1940 we reported on 106 gastroenterostomies followed for 7.1 years and found at that time that only 24.5 per cent of the patients were cured. At this time the diagnosis was gastrojejunal ulcer in 18.8 per cent and in 5.6 per cent the roentgen findings and symptoms suggested a gastrojejunal ulcer which made a total of 24.4 per cent of the cases in which there apparently was suffering from gastrojejunal ulcer. One would naturally ask why we encountered such a high percentage of failures and it is our feeling that this is directly related to the pathologic process which was encountered at the time of the original operation.

We are convinced that gastroenterostomies done on uncomplicated ulcers will give a far higher percentage of good results than those which we have reported because one would be dealing with an ulcer in the early stages which has not penetrated the wall and involved the adjacent viscus. Therefore the problem is merely healing of the primary ulcer and it one is fortunate to avoid a gastrojejunal ulcer the results will be quite satisfactory. But, likewise, excellent results are obtained in this type of case from medical management and surgery is not indicated.

The discussion of the surgical management of an ulcer rests on the pathologic process encountered and it is difficult to evaluate the pathologic process in the adjacent viscus unless a subtotal resection has been performed. During the five year period from 1928 to 1932 we had occasion to do twenty-nine gastroenterostomies for duodenal ulcers. The pathologic

process encountered in these cases was described as being an anterior duodenal ulcer in 14 instances, posterior in 13 and both anterior and posterior in 2. The age of the patient and duration of the symptoms were the same for the gastroenterostomy series and the subtotal series, namely 37.1 years for the former and 37.1 years for the latter, and the symptoms were present for 5.4 years in the former and 5.3 years in the latter. One would expect to encounter similar pathologic processes in the two groups, but the subtotal findings did not confirm this.

pain, which is not due to the ulcer but to the associated pathologic condition which has just been discussed, namely chronic pancreatitis. Seldom have we found it necessary to recommend surgical intervention for massive recurrent hemorrhage without pain. The long-standing ulcers presenting severe pain and massive hemorrhage constitute definite indications for surgical intervention. But the massive hemorrhage without pain in a duodenal ulcer seldom, if ever, should have surgery recommended.

As previously stated, we have referred for operation 14 per cent of the patients who had not been operated on. There is one type of case at the present time in which operation is so frequently advised that in our experience is not justified, namely the obstructing duodenal ulcer without pain. From our observation, the so-called stenosing or obstructing duodenal ulcer which does not involve severe pain never needs to be operated on provided previous surgery has not been done. These patients can be handled most satisfactorily by diet and antispasmodics.

During the past nine years, from 1933 to 1941 inclusive, we have not seen a case in which gastroenterostomy has been indicated. We can conceive of only one condition which is a true indication for gastroenterostomy and that is one in which the patient has previously had a perforated duodenal ulcer with a simple closure and a scar tissue stenosis of the pylorus has resulted from the operation. This type of case can be most satisfactorily handled by gastrojejunostomy. We have encountered 1 such case, but that antedated 1933. These patients would be essentially free from pain, but one must remember that these lesions do not conform with so-called primary obstructing or stenosing ulcer but result from previous operative intervention.

The question of mortality in stomach surgery always is a matter of prime importance. In a series of 102 cases of subtotal resection done by the senior author there were five deaths, one of these can be attributed to pneumonia while the other four can be attributed to peritonitis. It should be emphasized that of these 102 patients, 33 had had previous gastric surgery, including eight patients having had perforated ulcers which necessitated subtotal resections at a later date for the relief of pain. Again, in considering mortality, one must remember that this group of patients is taken from a municipal hospital where the patients seldom had special nurses, we wish to stress that the average postoperative hospital stay for the 102 cases was nineteen days.

In our most recent review we³ analyzed the end results of 97 cases of subtotal resection from our clinic, 64 were found to be cured and 24 improved. This group of postoperative patients made 1,822 visits, or 18.8 visits per patient. It is our feeling that evaluation of results in stomach surgery, unless the patients are personally seen at frequent intervals, will give very misleading results. Patients will frequently have complaints which after a few months they have forgotten, and if they are seen only at long intervals these flare-ups are not remembered. These 104 patients averaged 2.9 years of postoperative observation.

TREATMENT OF JUXTAPYLORIC ULCER WITH OBSTRUCTION

COMBINED USE OF THE ALUMINUM HYDROXIDE DRIP AND THE WANGENSTEEN ASPIRATOR

V. C. ROWLAND, M.D.
CLEVELAND

Pyloric obstruction, partial or complete, is one of the common handicaps in the prompt and effective medical management of active peptic ulcer. Vomiting of hyperacid material, distention, pain, anorexia and general distress preclude any adequate medication. The first recourse in the acute emergency is suction drainage, which gives striking relief. This alone, however, leaves the acidity unneutralized, leaves the ulcer untreated and, if used too long continuously, is depleting. The logical supplement is intermittent suction combined with the continuous astringent and antacid drip treatment. This may be done very simply by connecting the intragastric tube to a Y tube one arm of which leads to the drip apparatus and the other to a Wangensteen aspirator. By clamping off alternately one and the other, one can regulate at will the amount of suction or drip treatment.

In the practical application of this method suction is used until the stomach is emptied and the abdomen deflated, and then it is used only ten minutes out of each hour. The nurse in charge is instructed simply to clamp off the suction arm and unclamp the drip arm at the specified intervals. The second day ten minutes of suction and two hours of drip are used; the third day four hours, the fourth day eight to twenty-four hours, the length of the period being guided by evidences of retention in the aspirated material. When the suction arm can be clamped off for twenty-four hours without retention or distress the rigid intragastric tube may be removed and the soft collapsible tube used for the remainder of the aluminum hydroxide drip treatment.

Feedings are started early in this method—liquid while the suction is used and later frequent bland feedings as in the usual drip regimen previously published.¹ Sedatives should be used liberally in doses such as $\frac{1}{2}$ to 1 gram (0.03 to 0.06 Gm.) of phenobarbital every four hours. Antispasmodics are relied on to a less degree, although novatropine $\frac{1}{2}$ gram (0.005 Gm.) every four hours is usually helpful. Vitamins B and C are given hypodermically. Liquid petrolatum 1 ounce (30 cc.) two or three times a day is important to avoid impactions, and all opiates are avoided. One fourth of magnesium trisilicate suspension may be used with three fourths of aluminum hydroxide as a further guard against constipation.

Eighty per cent of ulcers are within 1 inch of the pylorus. Approximately 85 per cent of pyloric obstruction is due to spasm and edema. This is usually associated with hyperacidity, hypermotility and pain, enhancing the tendency to chronicity, hemorrhage, penetration and perforation. Hence the importance of prompt control in the acute exacerbation or recurrence of ulcer, especially with vomiting, since this is rarely a symptom of uncomplicated ulcer. Partial obstruction is frequent and easily overlooked. Chronic

Read in the Panel Discussion on Ulcer before the Section on Gastroenterology and Proctology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.
1. Woldman, E. E. and Rowland, V. C. Am. J. Digest. Dis. & Nutrition 2: 733 (Feb.) 1936.

ciatricial stenosis at the pylorus with dilatation and low acidity contrasts strongly with pyloric obstruction, is entirely surgical and is not referred to in this discussion.

Hemorrhage in obstructive ulcer not infrequently results after a number of days of vomiting and straining. After the acute stage, hemorrhage seems to be no contraindication to the use of the method described. Suction is of course used cautiously. The aspirate indicates at once any fresh bleeding. This usually does not occur when erosion and digestion are suspended by constant neutralization. The continuous bleeding of the larger spurting artery protruding from the base of an ulcer of course precludes the use of the tube.

The severe ulcer with peritoneal irritation distention or suspected subcutaneous perforation, after the surgical stage and treatment by starvation, infusions and siphonage may be managed advantageously by the combined drip and siphonage method. Here, however, much more caution is necessary. All signs of peritonitis must be allowed to disappear before any drip or feedings are started.

If there is the added suspicion of a malignant condition by x-ray examination in an obstructing prepyloric lesion a therapeutic test may be more promptly and effectively carried out by the combined method. Presumptive evidence is again obtained by the characteristics of the aspirate, the rates of subsidence of obstruction and of disappearance of pus and blood. These changes are surprisingly rapid in purely inflammatory lesions. After control of spasm and edematous obstruction and healing of an open ulcer many of these patients may go for years without recurrence, provided, of course, they cooperate as after any ulcer management. Persistence of obstruction for longer than a week suggests advanced scarring or a malignant growth. In this event the patient is prepared by the siphonage in the best way for gastroscopy and follow-up roentgen therapy or surgery.

It should be borne in mind that considerable fibroplastic thickening occurs in the more prolonged case of partial obstruction. After satisfactory medical treatment, the x-ray examination may show a residual deformity suggestive of malignant growth or of healing of the peptic ulceration in an initially malignant lesion. It takes time even after healing of the ulcer for the inflammatory thickening to absorb. In 1 such case after aluminum hydroxide drip therapy resection was carried out on the suspicion of carcinoma in the second x-ray examination. The specimen showed a healed shallow crater with inflammatory induration around the rim. The pathologist at the clinical-pathologic conference demonstrated the continuity of newly formed epithelium over the floor of the crater and no suggestion of a malignant condition.

When convincing evidence of a malignant growth cannot be obtained by roentgen examination and gastroscopy, it seems justifiable in the light of the end results of radical surgery such as those presented here two years ago by Dr. Sara Jordan² to keep the suspected ulcer under conservative management for a reasonable time, to make a series of tests for occult blood in the stool, to use continuous drip treatment a second time if necessary and to repeat the x-ray examination. Since the danger of malignant degeneration occurring in an initially benign ulcer is rather remote, the risk of delaying operation in primary car-

cinoma is probably less than the risk of radical surgery and its sequelae. Persistent painstaking follow-up, however, is necessary to be safe with conservative management.

The obstructive factor, more commonly than is realized, contributes to the complications and the simulation of a malignant condition. Combined drip and siphonage treatment is especially adapted to the control of this factor.

CONCLUSIONS

1 Pyloric obstruction is an important factor in the failure of prompt and effective medical control of active ulcer. Obstruction increases also the tendency to hemorrhage, late perforation and intractability.

2 The combined suction and aluminum hydroxide drip treatment may be instituted at once, gives prompt relief, provides continuous antacid and astringent therapy is flexible and is adaptable to the needs of the individual case.

3 This method gives more prompt and decisive information in regard to the presence of cicatricial stenosis or a malignant growth and at the same time prepares the patient for gastroscopy, follow-up roentgen therapy or surgery when necessary.

JEJUNAL ULCERS AND RECURRENT HEMORRHAGES

AFTER PARTIAL AND SUBTOTAL GASTRECTOMY FOR PEPTIC ULCER

EVERETT D. KIEFER, M.D.
BOSTON

Postoperative jejunal ulcer occurring after subtotal gastric resection is a tragic disappointment in the treatment of peptic ulcer.

The hope that this radical operation would solve the problem of postoperative jejunal ulceration which had brought gastroenterostomy into disfavor has been displaced by the realization that this complication can follow any operation which joins gastric mucosa to small intestinal mucosa.

Partial gastrectomy was proposed as a more effective means of reducing gastric acidity, which has been shown conclusively to be an important factor in the production of postoperative ulcerations in the jejunum. At first the procedure appeared to be highly successful, since routine gastric analyses after partial gastrectomy seemed to indicate that anacidity had been achieved in nearly all cases. However, Klem¹ found that the gastric secretory response to a test meal was delayed in the partially resected stomach and that many cases, apparently anacid in a test lasting one hour, did produce appreciable quantities of free acid if the test was prolonged to a three hour period. Klem, Aschner and Crohn² found that immediate postoperative anacidity was present in 77 per cent of the gastric ulcer cases, but this was found in only 38 per cent of the patients operated on for duodenal ulcer. Berg reported that only 13 per cent of the patients with high preoperative acidity were rendered anacid by subtotal gastrectomy without vagotomy.

At the Lahey Clinic 141 patients were given tests postoperatively by means of a single specimen of gastric contents taken forty-five minutes after an Ewald test meal. Of this group 96, or 68 per cent showed no free acid with this technic. However, when histamine was used as a gastric stimulant 16 out of 23 patients with a negative response to the Ewald meal were found to have free acid. Although the bulk of the patients were not given tests with histamine, these findings indicate that the secretion of free acid persists after subtotal gastrectomy in an appreciable number of cases, provided the stimulation is adequate. Certain mechanical factors such as the rapid emptying of the gastric stump through a wide stoma or the reflux of jejunal contents by the same route tend to make anacidity more apparent than real. The highest percentage of cases

in gastrointestinal physiology. It more nearly corresponds with the experimental ulcer of Mann and Williamson than do the primary ulcers in either the stomach or the duodenum. Mann³ recognized three etiologic factors: the traumatic factor, the acid factor and the factor of tissue susceptibility. Trauma may well be important in postoperative jejunal ulcer by causing the initial break in the jejunal mucosa. Forceful expulsion of more or less abrasive food material by the muscular stomach with direct impingement on the soft, velvety, easily traumatized small intestinal mucosa is likely to produce erosions which could be turned into ulcers by the action of active gastric juice. These injuries probably occur just as frequently in patients operated on for gastric ulcer or for carcinoma yet it is well known that postoperative ulcers do not develop,

TABLE 1—Clinical Features of

Case	Name	Sex	Age	Preoperative Lesion	Preoperative Acidity After Ewald Meal	Operation	Postoperative Regimen	Interval Before Onset of Symptoms
1	Valenti	♂	37	Duodenal and jejunal ulcer	Free HCl 63 total 190	Finsterer resection $\frac{1}{2}$ of stomach posterior Polya	Fair diet smoking	11 months
2	Whitney	♂	49	Duodenal ulcer	Free HCl 51 total 91	Finsterer resection $\frac{1}{2}$ of stomach anterior Polya	Good diet no smoking	2 months
3	Palmer	♂	48	Duodenal ulcer	Free HCl 57 total 74	Finsterer resection $\frac{2}{3}$ of stomach anterior Hofmeister	Fair diet moderate smoking	21 months
4	Raleigh	♂	37	Duodenal and jejunal ulcer	Free HCl 69 total 89	Finsterer resection $\frac{2}{3}$ of stomach anterior Hofmeister	Fair diet no smoking	4 months
5	Hunt	♂	50	Duodenal and jejunal ulcer	Free HCl 26 total 68	Finsterer resection $\frac{1}{2}$ of stomach anterior Polya	Good diet no smoking	5 months
6	Montano	♂	38	Duodenal ulcer	Free HCl 18 total 61	Finsterer resection $\frac{1}{2}$ of stomach anterior Hofmeister	Fair diet moderate smoking	7 months
7	Campbell	♂	49	Duodenal ulcer	Free HCl 72 total 91	Finsterer resection $\frac{1}{2}$ of stomach anterior Hofmeister	Good diet no smoking	9 months
8	Quinn	♂	40	Duodenal and jejunal ulcer	Free HCl 47 total 66	Resection 1st portion of duodenum and $\frac{1}{2}$ of stomach anterior Hofmeister	Good diet moderate smoking	3 months
9	Calfee	♂	40	Duodenal ulcer	Not done	Resection 1st portion of duodenum and $\frac{1}{2}$ of stomach anterior Hofmeister	Normal diet moderate smoking	9 months
10	Leader	♂	48	Duodenal ulcer	Free HCl 67 total 89	Resection 1st portion of duodenum and $\frac{1}{2}$ of stomach anterior Hofmeister	Normal diet moderate smoking	20 months
11	Samuel	♂	46	Duodenal and jejunal ulcer	Free HCl 66 total 81	Resection 1st portion of duodenum and $\frac{1}{2}$ of stomach anterior Hofmeister	Fair diet moderate smoking	23 months
12	Tiekells	♂	46	Duodenal ulcer	Free HCl 59 total 62	Resection 1st portion of duodenum and $\frac{1}{2}$ of stomach anterior Hofmeister	Good diet no smoking	1 month

showing free acidity is obtained by a technic which provides for keeping the patient lying flat in the supine position while fractional specimens of gastric contents which pool in the fundus are withdrawn at fifteen minute intervals for at least two hours after stimulation with histamine. Figure 1 shows a typical response to an Ewald meal and indicates that only a small amount of free acid is produced during the first hour. When the test was continued with the additional stimulus of histamine the free acid rose to 90 and showed no tendency to fall within the second hour.

The emphasis on postoperative acidity is due to the fact that of all known possible factors persistent hyperacidity after operation stands out as the most important one bearing on the etiology of postoperative jejunal ulcer.

Except in rare instances jejunal ulcer is not a primary disease but is a lesion produced by the operative changes

apparently because postoperative anacidity is practically constant.

Tissue susceptibility apparently increases with the distance from the pylorus, indicating that mucous membrane that is not accustomed to the direct exposure to gastric juice is more prone to ulceration. Little is known regarding variations in tissue susceptibility between individuals. Therefore, persistent acidity after operation remains the only known factor found consistently in relation to postoperative ulcer.

The incidence of jejunal ulcer following subtotal gastrectomy for peptic ulcer is not accurately known, and the reports that are available, like those pertaining to the incidence of jejunal ulcer after gastroenterostomy, vary widely. Reports of one or more instances of

3. Mann, F. C. The Chemical and Mechanical Factors in Experimentally Produced Peptic Ulcer. *S. Clin. North America* 3: 753 (June) 1925.

jejunal ulcer after partial gastrectomy are fairly common. Hurst⁴ collected 100 cases from the literature. Gatewood⁵ reported 3 instances of recurrence in a series of 30 patients who had subtotal gastrectomies. Garrett reported 2 in 26. Klein, Aschner and Cohn found an incidence of 4.3 per cent in a series of 210 patients operated on for duodenal ulcer.

This report includes a study of the postoperative follow-up in 222 surviving cases of subtotal gastric resection for peptic ulcer. These patients were operated on at the Lahey Clinic before Nov. 1, 1941, and follow-up data have been collected and evaluated by the department of gastroenterology in all but 5 cases (table 2).

There were 49 patients subjected to subtotal gastrectomy for gastric ulcer. Not a single one in this group presented any sign or symptom which could be

There were 6 additional instances in which a clinical diagnosis of jejunal ulcer was made and was supported by the roentgen demonstration of a pocket in the jejunal wall.

There was a third group which consisted of 8 patients who experienced one or more gross hemorrhages after operation but in whom no ulcer was demonstrated. These were diagnosed simply as postoperative hemorrhage.

When the 27 cases of duodenal ulcer plus gastroenterostomy plus jejunal ulcer were considered as a separate group there was found evidence of recurrent jejunal ulceration after gastric resection in 5 cases and postoperative hemorrhage occurred in 1.

The operative technique and the surgical methods used in these cases have been described by Lahey and Mar-

Table 2. Cases of Jejunal Ulcer

Symptoms	Postoperative Acidity	Roentgen Examination	Treatment	Reoperation	Results
Epigastric pain chiefly at night relieved by food, made worse by physical activity	Free HCl 5%, total 70	Right stomach crater in distal loop	Medical regimen in hospital		Symptoms relieved, x-ray negative
Pain in right upper quadrant radiating to back relieved by food, made worse by walking, loss of weight, anemia	Free HCl 80, total 83	Large crater in jejunum	Medical regimen in hospital		Recurrent pain, severe hemorrhage
Sudden severe pain in left costal margin without relation to meal, relieved by soda	Free HCl 29, total 33	Crater in jejunum opposite trauma		Resection of 1/2 of stump, excision of jejunal ulcer, anterior Polya	Relieved, no free acid after histamine
Pain in right upper quadrant, intestinal obstruction	Free HCl 39, total 170	Crater in jejunum		Resection of all but 1/4 of stomach, excision of jejunal ulcer	Recurrence of jejunal ulcer requiring reoperation
Severe back pain not relieved by food or alkali	Free HCl 28, total 66	Crater in jejunum		Excision of large jejunal ulcer penetrating pancreas	Died of postoperative hemorrhage
Severe pain in epigastrium radiating to back, some relief from food	Free HCl 70, total 6	Rigid stomach ulcer seen by gastroscopy		Resection of pyloric end of stomach, excision of jejunal ulcer	Relieved
Epigastric distress, several severe hemorrhages	Free HCl 60, total 68	Crater in jejunum		Resection of part of stump, excision of jejunal ulcer	Relieved, free acid present
Severe umbilical pain radiating to back, night pain relieved by food, hemorrhage	Free HCl 24, total 41	Crater in jejunum	Medical regimen in hospital, long period at home		Relieved
Epigastric distress, gross hemorrhages	Free HCl 69, total 83	Crater in jejunum	Medical regimen at home		Some relief
Pain in left upper quadrant chiefly at night, relieved by food	Free HCl 106, total 170	Crater in jejunum	Ambulatory regimen		No relief
Epigastric pain, hemorrhage	Free HCl 26, total 40	Crater in jejunum	Treated elsewhere		
Severe epigastric pain, hemorrhage	Free HCl 61, total 70	Crater in jejunum		Resection of portion of stump, excision of jejunal ulcer	Recurrent pain, relieved by medical regimen, free acid present

considered evidence of a recurrent ulcer. The gastric acidity was measured postoperatively in 30 cases and a small amount of free acid was found in 3.

The total incidence of jejunal ulcer and postoperative hemorrhage was found in the group in which the original lesion was a duodenal ulcer. Some of these patients had had surgical treatment before and already had a jejunal ulcer after a gastroenterostomy. In the 173 cases in this group, which included 27 cases of jejunal ulcer and gastroenterostomy before resection, there were 6 cases, 3.4 per cent, in which jejunal ulcer followed subtotal gastrectomy and was verified by laparotomy. In fairness to all points of view, only those jejunal ulcers which were found at operation were considered verified ones.

shall.⁶ Briefly, in most cases the operation consisted of resection of the first portion of the duodenum and about three-fourths to four-fifths of the stomach with a modified Hofmeister anastomosis.

In 30 cases, because of technical difficulties and then attendant risks, the duodenum and pylorus were not included in the resection, the distal transection being placed proximal to the pylorus, as recommended by Finsterer in cases in which removal of the duodenum is too dangerous. In this group there were 7 recurrent ulcers and 3 cases of postoperative hemorrhages. This relatively high incidence of unsatisfactory results has led to speculation regarding the role of the pylorus and antrum, since there is evidence that there is a hormone evolved in the pars pylorica which stimulates the fundic glands to produce acid. However, actual evidence indi-

cating that the nonremoval of the pyloric end of the stomach was solely responsible for the recurrence of ulcer is rather meager. A postoperative gastric analysis after an Ewald meal was done in 24 cases of this group with the finding of free acid in 13 cases, which is approximately the same proportion as that found in

Fig 1—Gastric secretory response to an Ewald meal and to histamine fifteen days after subtotal gastric resection for duodenal ulcer

the combined group of duodenal ulcer cases. The fact that the surgeon had decided against an attempt to remove the pylorus was indication that this group represented a particularly severe grade of peptic ulcer and might be expected to show a higher percentage of recurrences.

The clinical features of jejunal ulcer after partial gastrectomy do not differ from those of jejunal ulcer after gastroenterostomy.

The lesion is a deep penetrating crater usually situated in the wall of the jejunum directly opposite the stoma or in the efferent limb not far from the anastomosis. The most important feature of the symptoms of this type of lesion is severe pain, which is usually located in the back but occasionally in the left flank

TABLE 2—Incidence of Postoperative Jejunal Ulcer and Hemorrhage After Subtotal Gastrectomy for Peptic Ulcer (Two Hundred and Twenty-Five Cases)

Operation for gastric ulcer	
Total number of cases	49
Jejunal ulcers	0
Postoperative hemorrhage	0
Operation for duodenal ulcer	
Total number of cases (includes 27 cases with jejunal ulcer after gastroenterostomy*)	173
Jejunal ulcers proved by operation	6 (3.4%)
Jejunal ulcers diagnosed clinically and by x ray no operation	6 (3.4%)
Postoperative hemorrhage no ulcer demonstrated	8 (4.6%)

* Duodenal ulcer combined with jejunal ulcer (gastroenterostomy for duodenal ulcer)

Total number of cases	27
Jejunal ulcers proved by operation	2
Jejunal ulcers diagnosed clinically and by x ray no operation	3
Postoperative hemorrhage no ulcer demonstrated	1

or left side of the abdomen. The characteristic relationship to food intake shown by peptic ulcer is often absent. In fact, the character of the pain is apt to divert the physician's attention away from the gastrointestinal tract. The pain comes on at irregular times, often related to body movements, position or exertion. Sometimes the radiation is such as to suggest left ureteral colic. Left-sided pleurisy may be thought to be the cause of the pain. The severity of the pain is

often striking. It may come on suddenly as an excruciating knife-like thrust requiring morphine for relief. Gross hemorrhage occurred in 6 out of 12 cases and chronic occult bleeding was present in all. The onset of symptoms in this type of case occurred as a rule from one to nine months after operation. In only 3 cases in the group was the onset later than a year after operation.

The clinical features of 12 cases of jejunal ulcer are shown in table 1.

All patients in this group were males. The fact that most of these patients were operated on for long-standing, chronic, intractable ulcers accounts for the high proportion of patients falling within the age brackets of 37 to 50.

The preoperative response to an Ewald test meal was hyperacidity in all cases except those in which there was a functioning gastroenterostomy. Without

Fig. 2—Characteristic crater of a large jejunal ulcer located opposite the stoma. Although the gastric stump is small, indicating a high resection, the gastric free acidity in this case was 99 units after stimulation with histamine.

exception, these patients showed free acid postoperatively when tested with an Ewald meal and when histamine was used as a stimulant of the partially resected stomach; the acid secretion was uniformly high.

Severe or moderately severe pain was a prominent complaint in 9 cases.

The postoperative regimen followed by these patients was quite good in general. In only 2 cases could gross indiscretions in diet be offered as a possible cause of recurrent symptoms. Approximately one half of the patients smoked after their operations. Some of the most severe postoperative ulcers occurred in patients who were well trained and who followed a reasonably careful diet and did not use alcohol or tobacco. In general, these patients did not eat pureed vegetables except for a few weeks after operation. Their diets were apparently well balanced and contained adequate

vitamins. Severe emotional strain was a definite factor in some cases. Strenuous physical exertion was thought to be important in an occasional case.

In addition to the group of patients in whom definite penetrating ulcer of the jejunum developed after subtotal gastrectomy there is another group who had recurrent gastrointestinal hemorrhages at varying times after operation (table 3). There were 8 cases in this group, and like the verified cases all occurred after operation for duodenal ulcer. The symptoms occurred from a few weeks to three years after operation. In all these cases pain or distress were minimal. The general health and well-being of the patient was usually good, and recovery after the hemorrhage was prompt.

It is interesting to note that the symptoms before operation were similar in general. In 6 of the 8 cases

gastric juice. Under favorable conditions healing takes place readily without the development of a crater which can be demonstrated by roentgen rays.

DIAGNOSIS

The diagnosis of postoperative jejunal ulcer may be readily suspected when the patient has gastrointestinal bleeding or complains of a recurrence of pain similar to that experienced before operation. Although the diagnosis may be strongly suspected on clinical grounds, it may be extremely difficult to prove. Substantial quantities of free hydrochloric acid after a test meal is circumstantial evidence of an ulcer. Strong evidence is the demonstration of a crater in the wall of the jejunum which occurs usually exactly opposite the stoma, apparently at the point of most prominent

TABLE 3—Clinical Features of Eight Cases of Postoperative Hemorrhage in Which Jejunal Ulcer Could Not Be Diagnosed

Case Name	Sex Age	Preoperative Lesion	Preoperative Acidity After Formal Meal	Operation	Post operative Regimen	Interval Before Onset	Symptoms	Post operative Acidity	Roentgen Examination	Treatment	Results
1 Dua	♂ 41	Duodenal ulcer	Free HCl 88 total 102	Anterior resection $\frac{2}{3}$ of stomach, posterior Polya	Fair diet moderate smoking	34 mo	Hemorrhage no pain	Free HCl 39 total 61	No ulcer demonstrated	Medical ulcer regimen	Relieved
2 Duh	♂ 37	Duodenal ulcer	Free HCl 77 total 95	Anterior resection $\frac{2}{3}$ of stomach, anterior Hofmeister	Good diet no smoking	16 mo	Hemorrhage epigastric distress at night	Free HCl 15 total 39	No ulcer demonstrated	Medical ulcer regimen	Relieved
3 Fin	♂ 41	Duodenal ulcer	Free HCl 70, total 84	Anterior resection $\frac{2}{3}$ of stomach, posterior Polya	Fair diet moderate smoking, some alcohol	27 mo	Hemorrhage epigastric distress	Free HCl 33 total 52	Narrow area in distal loop	Medical ulcer regimen	Relieved
4 Wood	♂ 41	Duodenal ulcer gastroenterostomy	Free HCl 39 total 53	Resection 1st portion of duodenum and partial gastrectomy	Good diet	10 mo	Several hemorrhages epigastric distress	Free HCl 26 total 35	No ulcer demonstrated	Treated elsewhere	No report
5 Fog	♂ 31	Duodenal and jejunal ulcer gastroenterostomy	Free HCl 34 total 64	Resection 1st portion of duodenum and $\frac{2}{3}$ of stomach, anterior Hofmeister	Fair diet moderate smoking	5 mo	Hemorrhage no pain	Free HCl 20 total 38	No ulcer demonstrated	Medical ulcer regimen	Relieved
6 Bow	♂ 31	Duodenal ulcer gastroenterostomy	Free HCl 35, total 78	Resection 1st portion of duodenum and $\frac{2}{3}$ of stomach, anterior Hofmeister	Good diet no smoking	19 mo	Several hemorrhages no pain	Free HCl 0 total 34	No ulcer demonstrated	Medical ulcer regimen	Relieved
7 An I	♂ 45	Duodenal ulcer	Free HCl 31 total 59	Resection 1st portion of duodenum and $\frac{2}{3}$ of stomach, anterior Hofmeister	Good diet	27 mo	Hemorrhage no pain	Free HCl 8 total 24	Not done	Medical ulcer regimen	Relieved
8 Vek	♂ 40	Duodenal ulcer	Free HCl 30 total 74	Resection 1st portion of duodenum and $\frac{2}{3}$ of stomach, anterior Hofmeister	Good diet no smoking	22 mo	Hemorrhage no pain	Free HCl 0 total 17	No ulcer demonstrated	Medical ulcer regimen	Relieved

operation was done because of multiple hemorrhages. In all a definite peptic ulcer of the duodenum was found at the time of the resection. Hemorrhagic blood dyscrasia was not noted except in 1 case in which a tentative diagnosis of allergic purpura was made.

Persistent gastric acidity was apparently a factor, since in 6 out of 8 cases free acidity was found postoperatively.

The roentgen examinations after the postoperative hemorrhages gave negative results except for occasional hyperactivity of the jejunum, suggesting irritation.

The morbid condition that accounts for these cases and some of the cases in which there are complaints of recurrent postoperative pain may well be an undemonstrated jejunal ulcer, but there probably exists in most instances a diffuse jejunitis or mucosal irritation with superficial erosions which are traumatic in origin but are aggravated by the persistent peptic activity of the

impingement of gastric contents as they are forced from the gastric stump (fig 2). As a rule it is difficult to demonstrate small excavations or acute nonindurated ulcers, although the jejunum may show signs of excessive spasm in such instances. Jejunal ulcer craters are best visualized by the use of only 1 or 2 teaspoons of a thick, easily spreading preparation of barium sulfate for the examination of the mucosal pattern of the gastric stump, stoma and adjacent loop of jejunum. If more barium sulfate solution is used the lesion is usually obscured.

Examination should be carried out with the patient in the upright, supine and prone positions, with the use of the fluoroscope and numerous "spot" films. Localized tenderness over the region is suggestive evidence. Areas of narrowing, rigidity, obliteration of normal mucosal folds and "funneling" of the stoma are presumptive evidence of ulceration.

I have had 1 case in which gastroscopic examination visualized an ulcer which was not frankly demonstrated by roentgen rays

Examination of the stools for occult blood is an important test and if occult blood is found consistently while the patient is on a meat-free diet it is distinctly good evidence of ulcer

All patients who complain of severe pain in the abdomen back or chest postoperatively, regardless of location or apparent dissociation from the digestive tract, should be studied for a penetrating jejunal ulcer

TREATMENT

The treatment of a postoperative jejunal ulcer is a difficult problem. Patients who do not show a penetrating crater by roentgen examination and some who do can be relieved by a rigid ulcer regimen consisting of bed rest, antacids, a smooth diet, mental relaxation and the elimination of tobacco and alcohol. A diet high in vitamins, particularly vitamin C, in cases presenting a hemorrhagic tendency and one which eliminates the possibility of traumatic excoriation of the jejunal mucosa seems to be a logical measure.

In the cases which present a definite penetrating crater in the jejunum medical treatment has been disappointing. Temporary relief has been obtained while the patient is at rest, but there is a tendency for pain to recur, with a resumption of physical activity.

Surgical excision of the perforating type of jejunal ulcer usually has been necessary for relief.

COMMENT

It is apparent that subtotal resection of the stomach and duodenum is not the final answer to the problem of duodenal ulcer in some cases. On the other hand, the results in gastric ulcer are gratifying with respect to permanent cure as well as to the elimination of a possible malignant condition.

The dictum "no acid, no ulcer" still holds but it would seem that the anacidity after the resection of the lower three-fourths of the stomach is more apparent than real, and in many cases there are probably times when the jejunal mucosa is subjected to gastric juice high in acid and pepsin.

Although the incidence of recurrent ulcer after radical resection of the stomach is lower than after gastroenterostomy, the postoperative ulcer problem is still unsolved. The type of case appears to be as important as the selection of operation, since it is noted that the group of cases in which a jejunal ulcer develops after gastroenterostomy also shows the highest incidences of postoperative ulcer when the patient is subjected to subtotal gastrectomy.

The evidence at hand seems to indicate that any procedure that does not remove the pylorus and the duodenal ulcer is inadequate.

For the present, at least, subtotal resection will remain the operation of choice for many ulcer cases which require surgery. However, in cases in which there is a high postoperative acid secretion, and particularly when there is a history of previous gastroenterostomy and jejunal ulcer, protective measures should be instituted postoperatively and maintained indefinitely.

As they stand, these figures constitute a challenge and an indication for the need of further advance in the surgical treatment of duodenal ulcer.

605 Commonwealth Avenue

ABSTRACT OF QUESTION PERIOD

What is the optimum amount and frequency of feeding of cream for an ulcer patient?

DR. HARRY SHAY, Philadelphia: The optimum amount is difficult to state for any one individual. I can answer that question best by stating that certainly milk has been found to be, from the standpoint of the neutralizing effect, as efficacious as any other of the substances or any drug suggested. It has been shown, for example, that milk can combine with its own volume of 0.3 per cent hydrochloric acid. The optimum amount is the amount that we usually use for these patients, varying of course from the beginning when feedings are given from 2 ounces of cream an hour, to lesser amounts as other foods are added to the diet.

Can you correlate the various psychosomatic factors in ulcer with your concept of gastric secretion?

DR. MAURICE FELDMAN, Baltimore: We could correlate the psychosomatic pattern in this respect, that the average case of ulcer occurs in young adults who are jittery, high strung and emotional and unable to adjust themselves. We feel that they are more susceptible to duodenal ulcer than the average group of cases. We feel that this group of cases if properly eliminated by the gastroenterologists in the Army, will lower the incidence of complications occurring.

What is the duration of one course of treatment by the drip method?

DR. ASHLER WINKELSTEIN, New York: In the moderately severe cases three meals a day are given and the drips between the meals during the night for three weeks or preferably four weeks and thereafter the night drip is continued for another six weeks preferably.

Why do you think the continuous drip therapy is more effective than the administration of medications by mouth during a period of twenty-four hours?

DR. WINKELSTEIN: The superiority of the milk drip is due to the fact that waking the patient during the night disturbs him acts as a stimulant to acid secretion and cannot be continued indefinitely. It has been found by Dr. Kirsner and Dr. Palmer that a large dose of aluminum hydroxide given every two hours during the night does not give a pH of more than 3, whereas with milk drip and aluminum gel drips we get 3.4 without peptic activity. It is impossible in our experience to control the intradigestive secretion in the daytime or during the night with any other form of therapy.

With the high incidence of ulcer and militarily limited practice how are you going to carry on?

DR. WINKELSTEIN: We believe that is one of the great advantages of the milk form of therapy for in private practice and even in hospital and outpatient practice we are able to teach the patients to carry out this therapy by themselves at home. I am destroying a fair percentage of my own personal practice by teaching the patients how to treat themselves instead of my treating them.

How often does alkalosis occur with soda in the H ml drip?

DR. WINKELSTEIN: In the early stage we studied the carbon dioxide combining power of venous blood and did not find in any instance over 60 volumes per cent. We have stated that milk soda is not preferable with alkaloses, advanced renal disease, and older conditions as emphasized by Dr. Jordan. We believe that in those cases the nonabsorbable alumina gel drips are preferable. [Dr. Winkelstein showed slides, the first of which illustrated the hypersecretion and hyperchlorhydria throughout the night in duodenal ulcer patients while on the Sippy therapy during the day. This high acidity during the night has been confirmed by Henning in Europe, Val Dez in Chicago and Dr. Sandweiss, who is about to publish a careful study on the same thing. The second slide was a statistical summary of 34 cases showing that the average pH of 1.5, which is about 60 clinical units is produced by all three forms of

drip therapy, bicarbonate, the aluminum hydroxide and aluminum phosphate, in which there could be no acid irritation or peptic activity. The third slide showed the same thing in individual cases, three curves, the duodenal ulcer with pronounced reduction of acidity with a drip after breakfast and during the night. The fourth slide showed a high curve of secretion, from 6.50 to over 60 throughout the night, with decided hypersecretion while the patients were on Sippy therapy during the day.]

Can you give a physiologic explanation for hypersecretion in ulcer?

DR J CARL THOMAS, Philadelphia: It has been suggested by Dr Ivy that the irritated intestinal mucosa associated with the duodenitis may give rise to production of histamine which is absorbed in the blood stream and therefore causes increased secretion.

If acid is important as a factor, should not acidity in the intestine rather than the stomach be controlled in duodenal ulcer?

DR THOMAS: Definitely. Recent work done in our laboratory by Dr Berk has emphasized that point, and the results will be published in due time.

Please explain the occurrence of duodenal ulcer and perforation after extensive burns in patients with normal stomachs.

DR THOMAS: That interesting question calls for a lot of speculation, but it has been shown that the continuous absorption of histamine, when large doses are injected subcutaneously in oil, will cause perforating duodenal ulcer in experimental animals. The view is prevalent that burns give rise to the absorption of histamine-like substances in the blood and that the burn shock which follows is the result of such absorption. Putting those facts together, it isn't difficult to imagine that an absorption through a burned area causes the continued action which is responsible for this.

How many achlorhydrias have you seen produced by surgical procedure?

DR REYNOLD E. CHURCH, New York: The only answer to that is in follow-up results on subtotal resections done by routine method with no special technique carried out. We had 46 per cent of the cases without free hydrochloric acid, and there was an average follow-up of 288 years.

What good is it to sever the vagal fibers to the stomach in surgical procedures for ulcer, when the cephalic, gastric and intestinal stimulating factors remain?

DR WINSTON STEIN: Years ago Dr Eugene Klem and I suggested to Dr A. A. Bergh that the postoperative acidity after partial gastrectomy was due to persistence of nervous phases of gastric secretion, which we thought we demonstrated in clinical studies. At our request Dr Bergh severed the anterior vagal fiber subphrenically over the cardia in about 40 patients. Thirty-six out of 40 patients developed postoperative achlorhydria, more than half immediately and some later. None of these developed a postoperative recurrent ulcer and none suffered any harmful results from the procedure. We advocate that surgeons operate on duodenal ulcer with high free acidity and, in addition to partial or subtotal gastrectomy, that they should not cut the vagal fibers but only the subanterior ones which may lead to harmful procedures in the abdomen.

How long after the subtotal gastrectomy did the jejunal ulcer develop?

DR EVERETT D. KIEFLER, Boston: In all but 2 cases they developed within a year after operation. The earliest one was within one month. Most of them were within one to nine months. In cases of simple hemorrhage, however, that were not diagnosed as ulcer, the hemorrhage seemed to occur at any time up to three and four years after operation.

What are the minimum indications for operation for a bleeding peptic ulcer?

DR KIEFLER: I take this to be in the presence of acute hemorrhage. The patient should be over 45 years of age and more particularly if, under medical management, he shows signs

of continued or repeated hemorrhage he should be operated on at once. That is the important criterion in my opinion, that he repeats his hemorrhage or continues his hemorrhage in spite of everything else we do.

Are we able to control bleeding by the drip method? What is your experience?

DR V. C. ROWLAND, Cleveland: Hemorrhage has not been regarded as contraindicating that in my experience. We believe in the use of the aluminum hydroxide drip. By suspending digestion the common experience is that bleeding does not recur.

Would you emphasize the need for diagnosis of cause of obstruction, whether prepyloric, postpyloric or lesser curvature ulcer?

DR ROWLAND: The diagnosis of obstruction is not as easy as might appear. In fact many obstructions are unrecognized. The x-ray examination may be misleading and denote vomiting and obstructive factors causing distention and pain and so called intractability.

If you believe in the conservative treatment of bleeding peptic ulcer, would you care to say how soon the operation was done? What influence has the time factor between onset of hemorrhage and operation?

DR JOHN M. BLACKFORD, Seattle: I purposely have not gone into any discussion in my paper with regard to the time for operation. We have a definite feeling that the operation should be undertaken only on patients past 45 with serious hemorrhage and that operation should be undertaken as promptly as possible if it is to be undertaken because patients operated on after six, seven or eight days give a bad prognosis.

What has been your personal result of the operation on elderly people?

DR BLACKFORD: I feel that two or three lives have been saved by operation. My experience is very limited.

Are you planning on it as a regular procedure?

DR BLACKFORD: I feel that in the serious cases it must be seriously considered and I usually do it.

What about your experience of medical treatment of acute perforated ulcer?

DR BLACKFORD: A local surgeon, Dr Bernard Mullen, became interested in a report of Dr Wangenstein published in 1925, in which he treated by aspiration 8 cases of acute perforated peptic ulcer. Dr Mullen undertook some of this work at our county hospital. Some of his friends also became interested, and to date they have treated 28 patients with acute perforations, 6 or 8 of whom had free gas shown by examination, in the abdomen. They have been treated by putting down a Levine tube and giving a patient occasional small sips of very dilute sodium bicarbonate solution. Only three deaths occurred. Dr Mullen feels that this is such a touchy subject that he has not published a report of his work, however. He feels that this might have a great deal of importance in military surgery because there will be many instances of acute perforation in the armed services, in which this apparently might be a life saving procedure.

Don't you think that an end to side posterior Pylva type operation will reduce the incidence of gastrajejunal ulcer?

DR KIEFLER: There are not enough figures to give any percentage of comparison, but this did occur in 1 or 2 instances in this group. Apparently it is not a safeguard or anything that will prevent jejunal ulcer.

In fatal cases over age 45 have you any figures on how many were due to hemorrhage per se and how many were attended by complicating diseases which were factors in the fatality?

DR JACOB MEYER, Chicago: I do not have such figures, however, this may be stated. At first I do not think that given a proper elevation and other conditions, arteriosclerosis or even coronary sclerosis is a contraindication to operation in the aged.

What was the cause of death after operation for bleeding peptic ulcer?

DR MEYER Various causes were encountered, varying from bronchial pneumonia in the young patients to peritonitis in others

Do you think the mortality rate of 28 per cent in patients over 45 with just hemorrhage would be improved if surgery should be done immediately in every case?

DR MEYER That is a hard question to answer. It is likely that in one's early experiences the mortality may be increased unless one makes a very proper selection of cases.

What are your criteria for distinguishing duodenitis from duodenal ulcer?

DR B. R. KIRKLIN, Rochester, Minn. Duodenitis without ulceration is a comparatively rare finding. We feel that in a duodenum with pronounced irritability, transient deformity due to spasm at one moment may be some deformity of the duodenal bulb at the next moment, a different type of deformity or none at all. Smooth contour and hyperirritability are the principal signs, x-ray signs, that we use in establishing the diagnosis of simple duodenitis without ulcer.

Have you any method of identifying the prepyloric ulcer in the presence of severe pylorospasm?

DR KIRKLIN Prepyloric spasm is the one thing that indicates the accurate identification of the prepyloric lesion more than any other one finding. Because of the prepyloric spasm common with almost all ulcers, especially those near the pylorus, it makes the identification of these that much simpler. Of course, one has to be satisfied with merely reporting that there is a lesion at the outer edge of the stomach or obstructing lesion or ulcerating lesion, unless one is certain that one is dealing with a peptic ulcer niche, one should not report it as a simple ulcer.

What are your criteria for the roentgenologic diagnosis of carcinomatous ulcer and how do you differentiate this from benign hyperplasia?

DR KIRKLIN We can't always do it—at least I can't. Some of the roentgenologic features that help differentiate benignancy from malignancy in a gastric ulcer are as follows: 1. In almost all benign gastric ulcers there is a pronounced gastrosplasm usually prepyloric regardless of where the ulcer may be in the stomach. With small ulcers there is usually not much spasm. 2. The contour of the ulcer niche in a simple ulcer is almost always smooth, hemispherical. The density of the niche is usually the same as that of the barium filled lumen of the stomach, while in malignant ulcers the contour may be irregular, ill defined and the density of the niche not the same that is less than that of the barium filled lumen. 3. One of the most important factors in the differential signs that the roentgenologist can enlist is not purely roentgenologic but clinical and that is the question of tenderness. I think that practically all peptic ulcers in our experience, benign peptic ulcers, are definitely tender to direct palpation, which we can do under fluoroscopic manipulation. On the other hand, most malignant ulcers are not tender to the erectile patient. Those are the x-ray findings that help us identify some of the ulcers that are malignant—and don't misunderstand me, because there are many ulcers that have no roentgenologic signs as far as I am concerned, that appear—they have nothing to indicate a malignant condition, yet from 10 to 12 per cent turn out to be malignant at pathologic examination.

Regardless of size, clinical picture and laboratory procedures, could you operate shortly after this diagnosis is made or would you delay for a therapeutic test of response to treatment?

DR KIEFER I would try a reasonably short period of medical treatment and watch the response. I believe that a period of two or three weeks is not too long to observe these patients. The ulcers all should disappear entirely in this time.

Clinical Notes, Suggestions and New Instruments

A NEW PRESUMPTIVE TEST FOR PROTHROMBIN DETERMINATION

ALEX W. ULIN, M.D. AND EMIL BARROWS, M.D.
CINCINNATI

We wish to present a new presumptive test for determining the prothrombin level in whole blood.

This method utilizes a drop of blood obtained simply by finger prick. Too often on desperately sick patients whose veins have been obliterated by frequent previous venipuncture clinicians have been loath to do prothrombin determinations as frequently as indicated, or indeed they have been frustrated in this particular because of their inability to withdraw an adequate sample of blood. With infants and young children venipuncture is often a major difficulty. Thus a method which obviates venipuncture is desirable. Consequently we have elaborated a method which applies Gibbs's clinical blood coagulometer.¹

In 1924 Gibbs described a new type of clinical blood coagulometer which was simple and accurate. He referred to other types of coagulometers and described the principles involved. Briefly, a drop of blood, freshly drawn by stab puncture, will move freely on a clean wire, when the coagulation point is reached, the movement of the drop ceases abruptly, and this is a clearcut end point. By applying our knowledge of thromboplastin and determination of prothrombin, we were able to adopt the coagulometer as a presumptive method of determining prothrombin. In other words, we developed a standard technique for adding thromboplastin to the test drop of blood so that with an excess of thromboplastin we were in effect testing the prothrombin content of the blood.

APPARATUS AND MATERIAL USED

Simplified version of Gibbs's loop and the loop after Gibbs

1. The loop coagulometer. A simplified version of Gibbs's coagulometer, whose effective part is merely a thin platinum wire loop 5 mm in diameter with a 1 mm defect, is shown in the illustration. The loop is mounted on an aluminum handle protected by a guard and set in a glass tube from which it is easily removable. The platinum wire used is 0.011 inch in diameter. In the Gibbs coagulometer the defect in the circumference of the loop is placed well away from the junction of the stem and the loop. Such a loop, more difficult to construct, would be more efficient in use. We are now using such a loop (B) with a wire 0.024 inch in diameter.

Because of the ease of its construction, we had a platinum wire fashioned into a loop (A) so that the gap was located between the end of wire and stem junction. However, the principle of operation remains the same, that is, when such a loop is drawn through a drop of blood so that the gap is last to leave the drop, the film of blood that naturally forms in the loop is disrupted and a globule forms on the wire. It

Mr. Joe Thuering in the Surgical Instrument Department of the hospital gave technical assistance. The William S. Merrell Company, Cincinnati, also assisted in the work.

¹ Gibbs, Owens S. A Clinical Blood Coagulometer. Quart. J. Med. 17: 312 (April) 1924.

is important to have the loop perfectly formed, smooth and absolutely clean

2 **Thromboplastin** This is extracted from dried rabbit brain according to the method of Quick. There is one exception, however, on which we shall report at another time and that is that the activity of the thromboplastic substance can be maintained for a much longer period of time if the supernatant fluid containing the extract is not separated from the residue. We keep the extract in the same tube in which we kept the extraction at about 4 C. A cotton plug is placed in the tube and tamped down gently in order to separate filtrate from residue.

3 **Thromboplastin dispenser** Any dropper with a tapered delivery tube that will dispense a medium size drop.

4 **Bard-Parker blade No. 11** to make a clean deep stab puncture.

5 **Alcohol lamp** to clean the platinum loop. After heating to red heat the platinum wire cools promptly and is ready for use.

6 **Stopwatch**

METHOD OF PROCEDURE

1 **Cleansing** The finger is cleansed with alcohol and dried thoroughly. Absolute dryness of the finger is essential because any remnant of a volatile cleansing substance will delay coagulation. The use of gauze to dry the finger is recommended. It is necessary to avoid cotton and other materials that leave particles of lint.

2 **Stab puncture** We have used fingers of adults and toes or heels of infants. The cut should be clean and deep and blood should flow readily with very slight pressure. Squeezing or milking the digit will accelerate coagulation.

3 **Application of thromboplastin** Subsequent to the stab puncture and the appearance of blood the wound is gently wiped dry and a drop of thromboplastic substance is placed directly on the puncture wound. A medium size drop about 0.04 cc. is best.

4 **Test drop** With slight pressure a drop of blood will well up from the wound into the drop of thromboplastin. The mixture of the two drops is completed by the loop and simultaneously the stopwatch is started. i. e. the active mixture of blood and thromboplastin is the beginning of our measured prothrombin time interval.

5 **Loop globule** The loop is pushed through the mixture so that the gap is the last part to leave. A single globule will form on the loop. Occasionally several small beads of blood will form. These can be converted into a single globule by gently tapping and rotating the instrument. Of prime importance is the size of the loop globule. Its dimensions must be such that its form is symmetrical. A large distorted globule will prolong coagulation. When the proper globule is formed the loop is placed in the protective tube.

6 For about ten seconds we do not rotate the instrument, so that we disturb as little as possible the physical factors involved.

7 **End point** The instrument is gently rotated and the test globule moves readily on the wire. The end point is indicated by cessation of this movement.

8 **Calculation** The coagulation time is recorded in seconds. The presumptive prothrombin level, expressed in percentage is determined by comparison with the coagulation time of a normal control.

$$\% \text{ prothrombin of patient} = \frac{\text{Clotting time of normal}}{\text{Clotting time of patient}} \times 100$$

RESULTS

1 By using the presumptive loop method the prothrombin time for control patients varied from day to day between seventeen and twenty one seconds. Diluting the thromboplastin did not give as consistent results as the straight extract.

2 In patients with abnormal prothrombin our method checked with results obtained by the Smith "bedside" test.²

² Ziffren S. E., Owen C. A., Hoffman G. R. and Smith H. P. Control of Vitamin K Therapy. Compensatory Mechanism at Low Prothrombin Levels. *Proc. Soc. Exper. Biol. & Med.* 40: 595 (April) 1939 cited by Smith H. P., Ziffren S. E., Owen C. A. and Hoffman, G. R. Clinical and Experimental Studies on Vitamin K. *J. N. M. A.* 113: 880 (July 29) 1939.

3 The coagulation time is shortened by squeezing the digit when the wound is not clean cut, and with consecutive drops.

COMMENT

In checking the accuracy of the loop test we judged by our ability to duplicate results on the same patient using different stab wounds. Often if the blood flows freely the same wound can be used for a check determination. However, ordinarily the first drop gives the most prolonged coagulation time and represents the truest value. Apparently the thromboplastic substance present in the tissue juices affects the coagulation time even in the first drop in spite of the most careful technique to avoid it.

Certain technical difficulties are easily overcome by practice, thus the uniformity of the stab wound, the size of the drop of blood and the formation of an even globule on the loop. We as yet have not correlated the effect of hematocrit and specific gravity of the blood with results of the loop test. It seems reasonable to believe that these factors have some effect on the end point. Still, by dilution with the thromboplastic extract the influences of these factors are diminished. However, in spite of the variables, we have found that the test is accurate. It is a presumptive test and so its accuracy is clinically acceptable if the technique is careful, uniform and standard.

SUMMARY

The new presumptive test described here which utilizes a drop of blood for prothrombin determination is rapid and clinically accurate and can be done at the bedside.

PENILE ULCER CAUSED BY ENDAMEBA HISTOLYTICA

MAJOR HAROLD B. HERMANN, M. C. U. S. ARMY AND
FIRST LIEUTENANT LEONARD S. BERMAN, M. C. U. S. ARMY

Preclinical and clinical studies of *Endameba histolytica* infection are well known to the medical profession and have served materially in its proper prophylaxis and therapeutic control. While the pathology of this clinical entity has received considerable attention, infection of the penis by the *Endameba histolytica* organism is practically unknown. The case reported here is unusual not only because of its rarity but because of the difficulties in diagnosis and prompt response to specific therapy. Only 1 case of a similar nature has been reported in the literature. Amebiasis occurs quite commonly in the southern United States. Our patient was a native of Florida. Infection takes place essentially by way of the mouth. The active vegetative endamebas live in the tissues of the intestinal wall, where they ingest blood corpuscles and multiply by division. In the primary amebic lesions the amebas make their way into the follicles of the large intestine where they multiply and thrive. Partly by pressure and partly by the secretion of a cystolysin they make their way into the interglandular tissue and produce a small amebic abscess of the submucosa. In time this abscess ruptures and becomes an ulcer. A certain proportion of amebas leave the ulcers they produce, enter the bowel, encyst and pass out in the feces. Occasionally, however, the vegetative amebas may migrate from their site of election in the bowel wall and, as tissue invading organisms, enter the venous system and are transported to the liver and occasionally to the spleen, brain or lung. In this process they become unable to complete their cycle of development observed outside the body. Precystic and cystic stages are not known to develop in this region, however, great quantities of cysts were seen in the exudate from the penile ulcer in the case presented.

From the Section of Urology, Tilton General Hospital, Fort Dix, New Jersey.

Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the contents of this article.

REPORT OF CASE

W H, a white soldier aged 25, admitted to the Station Hospital, Mitchel Field, Aug 30, 1941, had noticed a "white spot" on the under surface of the glans penis near the coronal sulcus, August 25, the spot appearing seven days after sexual exposure. The ulcer was not painful at first but gradually enlarged until it was almost a centimeter in diameter. At the Station Hospital *Hemophilus ducreyi* was isolated from the lesion, but dark field examination and the Wassermann reaction were negative. In spite of sulfathiazole therapy locally and orally, the lesion became larger and very painful. After six weeks the patient was transferred to the Tilton General Hospital.

On admission to this hospital the patient complained bitterly of penile pain. He also states that he had occasional episodes of diarrhea and stated that he had amebic dysentery two years before. Examination revealed a ragged ulceration of the entire glans penis. The ulcer had red undermined edematous edges and was covered with a glairy gray sticky exudate which was very tenacious and was wiped away with difficulty. Repeated bacteriologic studies of the lesion were negative for *H. ducreyi* and *Treponema pallidum*. Only secondary contaminants were found.

The Wassermann and Kahn reactions however, were positive at this time. Studies of the stools were persistently negative for endamebas. Following a biopsy obtained through a dorsal penile slit sulfathiazole therapy was started both locally and by mouth. Intensive antisyphilitic treatment was also instituted.

During the subsequent four months, the patient's condition showed intermittent improvement. The ulcer would heal to the point of being replaced by clean granulation tissue but would then regress with the reappearance of the characteristic glairy tenacious exudate. Carcinoma was considered but biopsy sections revealed nonspecific inflammatory tissue. Pain persisted which at times required morphine. In an attempt to divert the urinary stream as an aid to healing of the penile lesion a suprapubic cystostomy was performed. Following this procedure improvement took place but this was of only a transient nature.

On Feb 2 1942 a specimen of stool was found to contain *Endameba histolytica*. A regimen of emetine hydrochloride and carbarsone was instituted. During the next eight days the ulceration began to extend down the sides of the shaft. Amputation was tentatively considered when it was deemed advisable to look for amebas in the exudate from the penile ulcer. The exudate contained myriads of cystic forms of amebas, which were grown in pure culture.

As carbarsone is the amebicide most readily soluble it was applied locally as a 0.5 per cent solution. In twenty-four hours all pain had disappeared. At the end of seventy-two hours there was little exudate and small points of fresh granulation tissue appeared. From then on the patient's course was one of rapid healing with complete epithelization taking place.

COMMENT

Amebiasis of the penis is a very rare condition. A survey of the literature with the help of the staff of the Surgeon General's Library revealed only the case of Shih Wu and Lieu.¹ In that case there were no intestinal symptoms; the stools were negative for amebas and the penile ulcer healed rapidly with emetine given in the usual manner. It is interesting to note that the lesion in our case was spreading rapidly while emetine and carbarsone were being administered for the intestinal infection but responded quickly to the local application of carbarsone as a continuous wet dressing. We believe that the penile infection was secondary to the intestinal infection and that poor personal hygiene resulted in intermittent autoinoculation.

CONCLUSION

Amebiasis of the penis must be kept in mind in the case of any chronic indolent phagedenic ulcer of the penis which does not respond in the usual period of time to the accepted local and oral therapy.

Because it is axiomatic that the venereal diseases must be attacked wherever they exist, the provision of adequate control measures for these diseases in industry is important. Thus far however only scattered attempts at establishing such control have been made. Present control activities are restricted largely to a general program. They do not aim at specific population groups. Industry represents a great number of special population groups—a total labor force of fifty-three million men and women 14 years of age or older, in communities throughout the country.

A venereal disease control program carried directly to the public will provide for a large percentage of workers. But it will not reach them all nor is there assurance that patients will remain under treatment. If however the general program is implemented by control measures in industry, two benefits will accrue. The total number of patients brought under treatment will be increased and the treatment will be more effective because the employers may properly require that employees remain under treatment until "cured" as a condition of continued employment.

In its broadest outlines, a venereal disease control program in industry involves cooperation between four groups: the employer, the employee, the medical profession and the state and/or local health departments. The employer is interested in the health and well-being of his employees; the employee in the efficient performance of his job; the medical profession in furnishing diagnostic and treatment facilities for those workers who require medical care; and the public health department in providing certain fundamental facilities which have been developed for the general venereal disease control program and which may be employed to advantage in the program in industry.

Venereal diseases are costly to the employer. The extent of these costs is unknown, but there is sufficient evidence to indicate that they are sizable enough to justify vigorous action. From the standpoint of the employer's liability, sickness and injuries chargeable to

the venereal diseases contribute their proportionate share to the loss of time in production as well as the loss of money through compensation payments.

Venereal diseases are no less costly to the worker. He lives by his skill, and he is proud for the time he spends applying that skill. Untreated venereal disease keeps him away from work, impairs his skill, shortens his life. It is in his interests to avail himself of the advantages of venereal disease control measures.

Workers in many plants are provided with a full or part time medical service. The addition of venereal disease control measures would be a logical extension of the medical program. Syphilis and gonorrhea are two diseases for which medical science has developed satisfactory diagnostic, therapeutic and control procedures.

The health of the American worker has assumed a new public significance. Five years ago industrial health was the concern of health departments in seventeen states, whereas today more than three fourths of the states are engaged in rendering health services to industry. Never before has the importance of activities for maintaining the physical fitness of the worker so closely paralleled the importance of production itself.

Policies regarding the employment of persons infected with venereal disease differ widely. In some instances, in which blood testing has uncovered a number of venereal infections, short sighted employment policies have discriminated against the infected persons to the extent that they were unable to find or hold employment. On the other hand a number of organizations employ infected persons under provisions that have proved satisfactory to employer and employee alike.

In order to assemble current authoritative information and to formulate basic principles applicable to a program of venereal disease control in industry the Surgeon General has appointed an Advisory Committee to the United States Public Health Service.

OBJECTIVES OF VENEREAL DISEASE CONTROL PROGRAM IN INDUSTRY

A. MEDICAL AND PUBLIC HEALTH

1 To find and refer for proper medical management all cases of venereal diseases among workers in industry

- (a) To prevent the spread of venereal diseases through early and adequate treatment
- (b) To prevent the development of late disabling manifestations by arresting progress of the disease through adequate treatment
- (c) To bring contacts of infectious persons under medical observation

2 To establish equitable policies for the employment of applicants and continuation of services of employees who have venereal diseases

- (a) To assure adequate treatment by requiring that employment be made dependent on the presentation of satisfactory evidence by the employee that he is under proper medical management

3 To coordinate the community and industrial venereal disease control programs

B. EMPLOYEE

1 To improve the physical condition of employees

2 To reduce the number of workdays lost through illness or injury

3 To provide job placement in order that the services of individuals having syphilis or gonorrhea may be employed at work which they are physically capable of performing with profit to themselves and to their

employer, and without risk to themselves, to fellow workers or to the public

4 To prolong and increase the earning power of employees by increasing life expectancy

C. EMPLOYER

1 To reduce compensation costs

2 To lessen work interruptions and labor turnover

3 To enhance production by increasing the efficiency of workers

4 To minimize those personnel problems which arise from syphilis and gonorrhea as causes of ill health and nervous instability

PRINCIPLES AND METHODS TO BE EMPLOYED

Methods to be employed in carrying out a program of venereal disease control among industrial workers will vary according to the local situation. Consideration must be given to the facilities and services available from state and local health departments as well as to the size and number of industries in the area concerned.

In formulating a venereal disease control program for industry the committee recommends that certain agencies be consulted in order to assure agreement on all phases of fundamental policy. In order to effect such an understanding officers charged with the responsibility of this program in state health departments are urged to discuss their plans with the following statewide agencies: (1) the state labor department industrial commission or similar department of state government; (2) the industrial health venereal disease or other appropriate committees of the state medical society; (3) the associations representing employers; (4) the labor organizations and (5) the appropriate voluntary health and welfare associations. These agencies constitute a lever for action as well as channels through which information can be distributed to a large and responsible section of the population.

An advisory committee to state health departments composed of representatives selected from the aforementioned agencies should be organized. Such a committee could render invaluable assistance and would give continuity to the statewide program.

ADMINISTRATION OF THE PROGRAM

Responsibility for the administration of the program should be shared by the industrial hygiene and venereal disease divisions of the state health department.

The industrial hygiene division of the state health department is familiar with the type and location of industries in the state, the number of persons employed and the relationship of labor organizations. The venereal disease division is familiar with the basic considerations in the general venereal disease control program that will be required for a program in industry. The industrial hygiene division should assume an active role in the preliminary phase of the program. Subsequently this division can render valuable assistance in persuading plants to adopt suitable control measures. This may be accomplished as a part of the division's regular activities concerned with special studies, surveys and other contacts with industry.

A consultation service to industry should be furnished by the venereal disease division, providing detailed information necessary for the inauguration of programs in plants. This consultation service should include recommendations for specific control measures, diagnostic laboratory procedures, treatment facilities, educational material, epidemiologic and case holding services and free drug service.

EDUCATIONAL PROGRAM

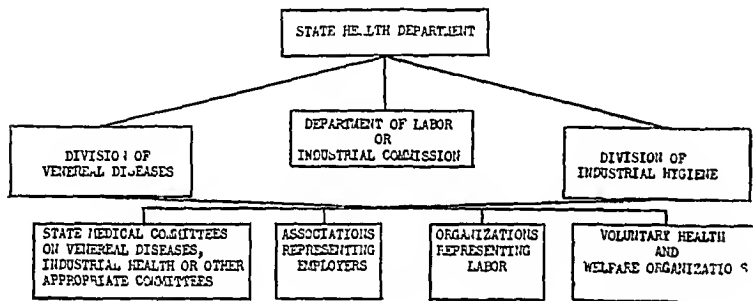

A venereal disease control program should not be inaugurated by an industry without a complete educational program. The homogeneity of the plant population will contribute to the success of an educational program, and many industries are equipped to undertake this responsibility with the assistance of state or local health departments.

The employee should be convinced that adequate treatment protects both his health and his ability to earn a living. He should be given a satisfactory general understanding of the venereal diseases, their cause, spread and cure. It is most appropriate that information about prophylaxis be included.

Employers should understand that not all cases of venereal disease are infectious and, further, that under proper treatment infected persons may be employed safely and profitably.

The only way in which both employer and employee can acquire such an understanding is through an educational program. It is best that this understanding be acquired prior to the introduction of venereal disease control measures.

It is important that the educational program be presented in an effective manner. The several mediums that are available should be carefully selected in accor-

Introductory phase in the development of a venereal disease control program in industry

dance with their suitability under varying circumstances. These mediums include posters, folders, pamphlets, articles published in management and employee magazines and, in addition, the presentation of the subject by speakers and motion pictures. Pamphlets and folders for distribution may be kept in wall racks located in places frequented by workers; they may also be distributed after lectures and motion picture showings. Posters may be displayed effectively on bulletin boards placed in plants, union meeting rooms and other locations where employee assemblages are held.

The education of a relatively small group in a plant population, such as foremen and shop stewards, has been found successful in disseminating information to the total employee population. Most health departments have available motion picture films, literature, posters and so on and are familiar with techniques that can be of material assistance to industry in conducting an educational program.

EXAMINATION

Health supervision of workers should include a careful history, physical examination, such special examinations as may be indicated, and laboratory tests. Included in the latter should be a serodiagnostic test for syphilis and, when indicated, a smear or culture for gonorrhea. In order that the venereal disease control program may be effective, preemployment examinations should be mandatory for all workers.

Many industries provide periodic physical examinations for their employees. The interval at which these examinations are performed will in many instances be dictated by the type of work involved. Some industries reexamine employees who are absent because of temporary layoff or illness. Laboratory tests for syphilis and gonorrhea should be made a part of the periodic, reemployment or "return from illness" physical examinations. When the interval between examinations is less than three months and no indication of infection exists, the tests need not be repeated. Under no circumstances should the interval between examinations be more than three years.

EXAMINATION RESULTS CONFIDENTIAL

The laws of most states protect the confidential nature of venereal disease information as regards the individual. It is of utmost importance that the results of the medical examination be considered confidential between the worker and the medical staff. This provision, of course, does not exclude the physician to whom the worker is referred for treatment or the health authorities in states where reporting of venereal disease is legally required. Information should be furnished to others only on the consent of the individual concerned or, failing this, on legal advice.

The industrial medical staff has a responsibility to fulfil in safeguarding the interests of the industrial organization and the fellow workers of persons found to have a venereal disease. In fulfilling this responsibility they should make proper recommendations to the management as to the physical fitness of the employee for work. For appropriate action, such recommendations do not require detailed medical information.

When routine practice permits the usual clinical record to be kept in an open file available to nonmedical personnel, separate venereal disease forms should be employed and filed in the medical department for the use of the medical staff only.

EMPLOYMENT POLICY

Many employers have thought that all persons with a venereal disease were infectious and should be denied employment or be discharged. When this policy is followed without due regard to what may be achieved through adequate treatment and careful case selection to eliminate those with serious disabling manifestations, the right to earn an income is unjustifiably denied.

There is no reason for denying employment to an applicant or for discharging an employee because an examination has revealed evidence of syphilis or gonorrhea, provided

- 1 That the employee agree to place himself under competent medical management
- 2 That, if the stage of the disease is infectious, employment should be delayed or interrupted until such time as a noninfectious state is established through treatment and open lesions are healed¹
- 3 That syphilis exists in a latent stage.

¹ The Subcommittee on Industrial Health and Medicine of the Health and Medical Committee of the Office of Defense Health and Welfare Services has established the following policy for determining employability of workers with clinical or serologic evidence of syphilis. They should be free from infectious and contagious lesions free from hazard to themselves and other persons and should be required to show satisfactory evidence that they are continuing under competent anti-syphilitic treatment regularly.

4 That, when disabling manifestations exist which would render such individuals industrial hazards to themselves, other employees or the public, employment may be deferred or denied

5 That provision be made, whenever possible, for occupational readjustments of employees who develop disabling manifestations that do not incapacitate them from performing some type of useful work

6 That workers with syphilis in any of its stages, and regardless of past or present treatment status, should be excluded from areas of toxic exposure, and that those having cardiovascular syphilis or neurosyphilis should not be exposed to such physiologic stresses as extremes of temperature, strenuous physical exertion or abnormal atmospheric pressure

7 That workers with gonorrhea should be allowed to work only under special medical observation during the administration of sulfonamide drugs

CONFERENCE FOR PERSONS WHO HAVE EVIDENCE OF A VENEREAL DISEASE

The applicant or the employee whose examination reveals evidence of a venereal disease should be called to the industrial physician's office for a conference

The worker whose infection is found to be communicable should be referred to his family physician or to a public clinic (for those who are unable to pay for private medical care) for confirmation of diagnosis and such treatment as may be indicated

An applicant found to have a communicable venereal disease should be advised that he cannot be considered for employment until he has received the amount of treatment required to render him temporarily noninfectious. Under similar circumstances an employee should be told that his employment will be interrupted until such time as he has complied with the same requirements. Such persons should be further advised that future employment is dependent on their willingness to continue under medical supervision until such time as an adequate amount of treatment has been administered to arrest the progress of the disease and/or effect a "cure"

When the examination of an applicant or employee shows evidence of a latent stage of the disease especially syphilis, wherein the only evidence of infection is a positive serologic test, no delay in suitable employment is justified. The worker should be told of his condition and referred to his family physician or public clinic for reexamination. The provision of continued treatment is the same as previously described

If the examination demonstrates a late manifestation of syphilis, such as cardiovascular syphilis or neurosyphilis, the worker should be told of his condition and referred for reexamination and treatment to such medical sources as have been mentioned. The question of employing or retaining the services of such an individual will depend on the extent to which the pathologic changes have progressed, the availability of a job that the worker is physically capable of performing and the question of industrial hazard

The conference at the industrial physician's office is an opportune time to inform the worker regarding the venereal diseases. In order that he may cooperate intelligently with the requirements of treatment in maintaining his employment status, it will be necessary that he understand in a general way something about the disease from which he is suffering. This may be explained to him by a suitable person on the medical staff and by literature which the patient can read at his leisure

FOLLOW-UP

It will be helpful and subsequently save considerable confusion if the industrial physician will provide the worker with a letter directed to his physician, stating

the circumstances of the examination, results and what is expected of the worker as regards regularity of treatment if he is to be employed. Whenever possible the plant physician should acquaint the worker with a reputable source for medical attention

Should the worker be employed or his services continued it is advisable that the industrial physician receive a record of treatment at about monthly intervals giving assurance that the patient is receiving appropriate medical attention

In the event treatment is interrupted and the worker refuses to resume treatment, the industrial physician should notify the management that the employee is no longer fit for work. The names of such individuals should be turned over to the health department for appropriate action in bringing them back to treatment

MORBIDITY REPORTS

As a rule, it devolves on the physician assuming the responsibility for diagnosis and treatment of patients with a venereal disease to submit case reports to the state or local health department. A primary function of the control program in industry is "case finding" and referral of persons with a venereal disease to competent sources for medical attention. Therefore it is the responsibility of the private physician or venereal disease clinic to submit such reports in most instances. However, in view of the urgent necessity of placing infectious syphilis and gonorrhea promptly under medical control, the plant physician making a tentative diagnosis of communicable syphilis or gonorrhea should without delay acquaint the appropriate health authority with the facts

HANDBOOK OF NUTRITION XV

THE PRESERVATION OF THE NUTRITIVE VALUE OF FOODS IN PROCESSING

EDWARD F. KOHMAN, PH.D.
CAMDEN, N. J.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

The prodigious increase in the consumption of succulent vegetables and fruits makes an interesting statistical study. A century ago most of the people of the United States regarded tomatoes as poisonous, and when children ate them inadvertently medication to counteract their "toxin" was not unusual. In 1918 Hess¹ recommended tomato juice as an antiscorbutic for 3 month old infants, and in later publications he stated that infants can tolerate twice as much tomato juice as orange juice. Today tomato juice is the leader in volume of an array of ever available fruit juices. Many a middle aged person who takes for breakfast a glass of orange juice comprising two or three normal size fruits can well remember when one such fruit in his Christmas stocking was his annual quota. Samuel Pepys once drank a whole glass of orange juice and was surprised that he did not become ill.

Less phenomenal growths have occurred in the consumption of all succulent vegetables, but their wide

distribution has eliminated seasonal and regional effects. How vegetables fit into present day nutritional aims has recently been pointed out in *THE JOURNAL*.² The average thiamine and riboflavin contents of a large number of vegetables are, respectively, 2.8 and 2.4 mg per thousand calories, whereas the amounts added to enrich flour are 1 and 0.7 mg respectively per thousand calories.

Even ancient man must have observed that certain root vegetables, such as parsnips, retain their edible qualities in the earth during extreme cold, while others, such as carrots, can stand only more moderate freezing and some are damaged by mild freezing. As a result, the vegetable pit was evolved as the most primitive method of processing succulent foods for their preservation, now exemplified in refrigeration under controlled temperature, humidity and atmospheric gases, and the recent modification designated "frosting" or "frozen foods."

Evidence that our vitamin age cannot lay claim to the first realization of the importance of the succulent and perishable foods in our nutrition is the evolution of the art of canning stimulated by the requirements of Napoleon's armies.

Paradoxical as it sounds, lack of heat (refrigeration) and application of heat (canning) have come to be the two major means of preserving perishable foods for use at all times and places. Today investigators are evaluating the efficiency of these in preserving essential

nutrients, emphasizing, as has recently developed knowledge on nutrition, the vitamins. A short review of the many experiments conducted on this point can only touch on the most pertinent, but these make it possible by inference and analogy to draw certain general conclusions.

EFFECT OF STORAGE AND COOKING ON VITAMIN C

Among the fruits, apples are prominent in lending themselves to cold storage. Recently, Eheart³ reported an average loss of 20 per cent of the vitamin C content during twelve weeks in experiments involving sixteen varieties of apples, two seasons and temperatures ranging from 35.3 to 37.9 F. A loss of one third occurred in from eighteen to twenty-four weeks. Other investigators have reported lower losses at 32 F. the practical minimum for apple storage. In cooking apples Eheart encountered losses which could be ameliorated by previously keeping the peeled and cored apples submerged in a 2.5 per cent salt solution for twenty-four hours the sodium chloride serving to keep the apples from darkening. The losses of vitamin C with three methods of cooking apples submerged and apples not submerged in salt solution are recorded in table 1. Kohman and Sanborn⁴ showed in 1924 that in commercial canning apples submerged for sixteen hours at 100m temperature

consumed all the oxygen within their tissues. This pretreatment is now accomplished in an hour at 120 F. Apples so treated may be canned without measurable loss of vitamin C and after a few months storage are more potent in this factor than similar apples stored under refrigeration.⁵

These experiments indicate that oxygen may play a distinctly destructive role toward vitamin C. They indicate but do not prove that heating is without effect. This was shown by increasing the normal processing of canned peas from twenty-five minutes to fifty minutes at 250 F.⁶ without there being any increased destruction of vitamin C. Many foods have reducing effects on oxidized (dehydro) ascorbic acid, as was strikingly demonstrated in peas⁷ and as the following unpublished experiment illustrative of a common behavior of many foods shows. Tomato juice was extracted without incorporating air and the ascorbic acid determined with 2,6-dichlorophenolindophenol. The juice was then divided into two portions, to one of which dehydro ascorbic acid was added. This did not affect the titration value. All the air was evacuated from both portions in pyrex glass flasks, which were sealed and heated for thirty minutes under boiling water. The titration value of the portion to which oxidized ascorbic acid had been added on cooling was 7.5 per cent higher than previously, whereas the other was unchanged. The fact that heating a food in itself need not be destructive of vitamin C must be kept in mind in considering the effect of cooking. Foods cannot be cooked without heat but they can be cooked in the absence of oxygen.

Floyd and Fraps⁸ have made practical application of avoiding oxidation of ascorbic acid in household cookery. In a large number of trials rapid cooking of turnip greens, maintaining a constant rise of vapors to blanket off the atmospheric oxygen, resulted in only 15.5 to 26.7 per cent destruction of vitamin C, while slow cooking caused 23.8 to 36.5 per cent destruction. Covering the cooking vessel had no protective effect.

Storage losses of ascorbic acid may be greater in some products than in apples. Maine grown Green Mountain and Irish Cobbler potatoes⁹ in a month's storage at 15.5 C lost 30 per cent ascorbic acid and in five months nearly 50 per cent. Lower storage temperatures for potatoes did not lower the losses. Loss in cooking becomes progressively greater with the following methods: steaming, boiling, baking and pressure cooking, but in no case did it exceed 25 per cent.

Clagett and Tottingham¹⁰ found that potatoes of several varieties grown in Wisconsin and stored for nine months at 4.5 C were 20 per cent lower in ascorbic acid content than Triumph and White Rose potatoes recently shipped to Wisconsin markets from the Pacific coast.

Schuenert and Reschke¹¹ made a comprehensive study in Germany of storing and cooking potatoes. Steaming was found to result in the least loss of ascorbic

and They assign to peeled, halved and steamed potatoes the following progressively smaller values with the advancing winter months: October, 18 mg per hundred grams, November, 15 mg, December, 13 mg, January 11 mg, February, 10 mg, March, 9 mg, April, 8 mg, and May/June, 7 mg.

Cabbage¹² stored in a home vegetable cellar at about 45 F and relative humidity of 55 for two months dropped from an original vitamin B₁ content of 45 Shearn-Chase units to 40 while after being cooked in generous amounts of water for ten minutes the unstored and stored fell respectively to 23 and 20 units. The vitamin C content in fall and spring was in the raw state, respectively 63 and 47 mg per hundred grams and after cooking 35 and 27 mg. Onions were found to change insignificantly.

Wellington and Tressler¹¹ reported an actual loss of from 10 to 30 per cent of vitamin C in cooking cabbage by various methods, but the cooking water extracted as much as 66 per cent. With carrots¹¹ loss of 14 per cent of their vitamin C was observed both when boiled and when steamed, but the vitamin C remaining after steaming was nearly all in the carrots whereas the cooking water extracted vitamin C in proportion to the volume.

Parsnips¹³ containing in the fall from 128 to 399 mg of ascorbic acid per hundred grams contained from 55 to 127 mg after winter storage in the ground. Fall and spring parsnips boiled unpeeled contained respectively an average of 30.5 and 83 mg of ascorbic acid per hundred grams while boiled after peeling they contained respectively 15.3 and 7 mg.

Harris Wissmann and Greenlie¹⁰ noted an average loss of 44 per cent in ascorbic acid in a number of vegetables at 41 F with relative humidity of 65 per cent as against a 26 per cent loss with a relative humidity of 93 per cent. While vitamin A and thiamine losses were less, they too were better preserved at the higher humidity.

Fitzgerald and Fellers¹ give the following average values, based on samples purchased weekly over a period of one year, for ascorbic acid in milligrams per hundred grams (table 2). Spinach¹³ at from 1 to 3 C lost its vitamin C very slowly whereas at room temperature it lost half in three days and nearly all in seven days. Peas,¹⁴ on the other hand showed no appreciable loss of vitamin C in six days at 1 to 9 C but considerable at 18 to 22 C. Lima beans⁹ shelled and unshelled at 0 C for eleven days lost respectively 58 and 31 per cent of their vitamin C content. Sweet corn²¹ purchased on the market does not suffer a significant loss in vita-

min C during its good quality history. Fresh corn cooked on the cob for eating (twelve minutes) lost 7 to 10 per cent of its vitamin C content. Mack, Tapley and King²² reported that wax beans lost 81 per cent and Kentucky Wonder 58 per cent vitamin C in six days at from 21 to 23 C and proportionately less in shorter periods. When wax beans were cooked to the done stage there was 62 per cent of the vitamin C in the drained solids and 26 per cent in the cooking water. The corresponding figures for Kentucky Wonder beans were 66 and 32, indicating a destruction of 12 and 2 per cent respectively.

Wheeler, Tressler and King²³ found that the ascorbic acid content of parsnips stored over winter in a pit dropped from 40 mg per hundred grams in the fall to 15 mg in the spring. Kale and New Zealand spinach lost half in four days at room temperature, while the loss in broccoli and cauliflower was only moderate. Wilting is always accompanied by serious loss of vitamin C.

Richardson and Mayfield²⁴ state that canned citrus juices and tomato juice after the can is opened lose no vitamin C in forty-eight hours, stored in a refrigerator. On the other hand Gould and Tressler²⁵ found that holding cooked cabbage at 1 to 3 C resulted in a loss of 50 per cent vitamin C in twenty-eight hours. The relative stability of vitamin C under such conditions has

TABLE 2—Average Milligram Values for Ascorbic Acid per Hundred Grams

	Broc- coll	Spinach	Peas	Aspara- gus	Snap Beans

been shown to be a characteristic of each product and not a function of the p_H or acidity, although influenced by them.

Bananas⁶ in three stages of ripeness contained, green, 61 mg of ascorbic acid per hundred grams, yellow, 63 mg and fully ripe 73 mg. House, Nelson and Haber²⁶ found no difference in the vitamin B₁ content of green, mature and vine ripened tomatoes, but the latter contained more vitamin A and vitamin C and more than the green mature picked tomatoes after they were ripened either in air or with ethylene.

Bartlett pears were shown by Tressler and Moyer²⁸ to drop from 9 to 4.9 mg of ascorbic acid per hundred grams during the first two months of storage at 30 F and thereafter fall but little.

While modern cold storage allows but little loss of food value as a consequence of respiration Benoy²⁹ has pointed out that with vegetables harvested in summer this may be a matter of serious proportions. Benoy

found that the carbon dioxide given off at 30 C during the second to the twenty-sixth hour after being harvested accounted for a loss of several per cent of the sugar from vegetables as follows: asparagus 137 per cent, lettuce 64 per cent, green beans 63 per cent, okra 52 per cent, carrots 45 per cent, tomatoes 32 per cent and beets 27 per cent. The serious aspect of this loss is that the flavor loss is of even greater proportions.

Oliver³⁰ points out that while water soluble constituents tend to be extracted in the boiling of vegetables, this loss may be minimized and the extractives used by keeping the water at a minimum and using it. All the vitamin A and from 70 to 75 per cent of the vitamin B₁ is retained, and while from 40 to 75 per cent of the vitamin C may be extracted less than 10 per cent is actually destroyed. In the present war period she points out, cooked vegetables constitute the chief source of vitamin C in England. While sodium, potassium and chlorine are extracted, they are dietetically unimportant and calcium is not extracted.

It is evident from the array of evidence cited that storage, cooking and other treatments to which vegetables and fruits are subjected may have a strong effect on their vitamin C value. It is evident also that these effects in many instances can be greatly minimized with care such as maintaining ideal storage and adopting appropriate cooking procedures. Heat in cooking is responsible for no serious vitamin C loss.

TABLE 3—International Units of Thiamine per Gram of Various Prepared Beans

	Michigan Beans	Cranberry Beans
Raw	17	0.9
Boiled in soaking water	30	2.9
Boiled in fresh distilled water	2.9	2.8
Soaked with soda, boiled in fresh water	2.8	2.9
Baked in soaking water	2.2	1.9

The reason for all these data presented on vitamin C is twofold. Of the vitamins, only in the case of C has it been possible to assay many foods by chemical means. Secondly, it is not uncommon, as Fenton³¹ has done, to use the retention of vitamin C in vegetables as a criterion of both quality and nutritive value in general.

EFFECT OF STORAGE AND COOKING ON OTHER NUTRIENTS

Data on nutritive value as affected by processing are not limited entirely to vitamin C. Aughey and Daniel³² report that there was no loss of thiamine in pressure cooking or boiling carrots, 16 per cent loss in baking potatoes, 20 per cent in pared and boiled potatoes, 22 per cent in boiled spinach, 9 per cent in simmered green peas, and 22 per cent if soda is added, 18 per cent in boiled beans and 59 per cent if soda is added, no loss in boiled navy beans, no loss in rolled oats or wheat cooked in a double boiler, 14 per cent loss in baking bread, 15 per cent in braised pork loin, and 43 per cent loss in roast pork. Kelly and Porter³³ give, in international units of available thiamine per gram, values of variously prepared beans of two types (table 3).

Lantz³⁴ found that neither the riboflavin nor the B₆ of pinto beans in the raw state was utilized by rats but both were well utilized in the cooked beans. The cooked beans had 8 micrograms of riboflavin per gram, with negligible quantities in the cooking water.

Oldham and Schlutz³⁵ demonstrated that heating meat, as in cooking or drying, renders the total iron of beef muscle as available to infants as equivalent amounts of inorganic iron, whereas the iron of unheated lean meat is generally agreed to be but poorly utilized. Mickelsen, Waisman and Elvehjem³⁶ found nicotinic acid and riboflavin stable to most cooking processes in meats and while thiamine suffers some loss it is least affected by frying in meat products. Hodson³⁷ found stewing, roasting, broiling or frying chicken had no effect on the riboflavin content.

BLANCHING FOR FROZEN AND CANNED FOODS

Many of the recorded experiments purporting to show the extraction effect of blanching are so far from actual conditions in commercial use that they are misleading. For example, Magoon and Culpepper³⁸ scalded 1,700 Gm of spinach and peas in 16,000 cc of boiling distilled water each for two and four minutes and green beans for four and eight minute periods. They state that in the case of spinach as much as 16 to 30 per cent of the total dry matter might under such conditions be extracted while in the case of green beans as little as 15 to 10 per cent was extracted, the values for peas lying in between. These, however, represent far more severe conditions than obtain in commercial blanching, in which a continuous stream of vegetables passes through a limited amount of water, which is replenished by the amount carried out by the vegetable. Under these conditions the proportion of water to vegetable is small and, obviously, the extractive effect thereby limited. Horner³⁹ noted that in blanching the losses of potassium ranged from 9 per cent in potatoes to 40 per cent in beans, phosphorus from 9 per cent in potatoes to 20 per cent in peas, and magnesium from 13 per cent in carrots to 25 per cent in peas and potatoes. Calcium is actually absorbed from the hard water used for blanching. As Oliver³⁰ has pointed out, extraction of potassium, sodium and magnesium is of no dietetic importance.

Some experiments on the extractive effect of blanching on the vitamin content are on record. Todhunter and Sparling's⁴⁰ values are given in table 4. Finke⁴¹ states that peas blanched for two minutes at 71 C had 4 micrograms of thiamine per gram and only 2.6 when blanched two or three minutes at 99 C.

There is so much inconsistency in these figures that one is not warranted in drawing far reaching conclusions. When in one case the ascorbic acid is 9.1 mg

per hundred grams with a six minute blanch and only 72 with a four minute blanch, then there is no basis for assigning any significance to another case in which it is 226 for the six minute blanch while it is 232 for the four minute blanch. As for the thiamine values of Fuike, it should be borne in mind that the feeding levels were 0.8 Gm and 1.2 Gm of peas a day and that the growth response for the 1.2 Gm dosage was so great that it had to be discarded when the thiamine level was evaluated. Yet there is sufficient evidence to warrant the statement that the greater part of the loss of vitamin C in canning occurs before the vegetable enters the can. This is in part due to extraction and in part to destruction. The matter is not so simple in frozen vegetables.

FROZEN FOODS

In recent years so-called frosted or frozen foods have appeared in retail form. Long before, however, it was customary to freeze certain fruits, chiefly berries, in barrels with or without sugar for the purpose of later converting them into jams, preserves and jellies. They were frozen without any precooking. When attempts were made to extend this freezing method to vegetables it soon became apparent that their normal flavor could not long be retained. Vegetables so frozen soon acquire what is commonly referred to as a haylike flavor. This was traced to the effect of enzymes whose activity is not completely inhibited even in the frozen state. It is a well known fact that abnormal activity of enzymes is aroused in a broken, raw vegetable cell. While much has been said about "quick freezing" as a means of reducing the size of ice crystals that may otherwise pierce or rupture the cells, the fact of the case is that the rupturing of the raw vegetable cell cannot be avoided, irrespective of the rapidity with which freezing is accomplished. I was convinced of this experimentally in 1928 by the use of liquid air as a freezing medium. So-called quick freezing of vegetables has virtues only in that it reduces the development of microorganisms as well as the action of atmospheric oxygen on the food, for example, on vitamin C.

It is now customary to blanch all vegetables before freezing to inactivate the enzymes and, for canning, blanching is necessary to expel air to avoid straining the hermetic seal in processing and to reduce the volume and enable compact filling. Temperatures up to or less than boiling water for one to a few minutes have been found adequate.

The gases in most vegetables are relatively low in oxygen content in comparison with the oxygen of the air, owing to the fact that the respiratory process constantly taking place in raw vegetables tends to use up the oxygen within the tissues. The blanching, as can be surmised from the relatively low loss of vitamin C in cooking vegetables, has no serious destructive effect on vitamins.

However, after the vegetables are blanched their oxygen-consuming enzymes are inactivated. Glutathione and hydrogenases in them no longer exert their reducing effect. The vegetables now become saturated with oxygen, this oxygen becomes a serious agent in vitamin C loss with storage if low temperatures are not at all times maintained. This is a matter of particular concern if frozen vegetables are thawed an appreciable time before being used. As the vegetables must be cooked for table use, the vitamin C may now suffer a greater loss than when raw vegetables are cooked directly for table use.

Rose,⁴² who reviewed the literature on frozen foods, has pointed out the importance of their being kept in the frozen state up to the time they are to be cooked for use. Fellers and Stepat⁴³ found the average ascorbic acid content of thirteen samples of frozen peas to be 131 mg per hundred grams, but after they had been defrosted from two to six hours the average value dropped to 41 mg. Todhunter and Sparling⁴⁰ claimed that peas thawed within thirty minutes lost 27 per cent in one hour thereafter. At 45°C 25 per cent was lost in twenty-four hours. This represents keeping the peas in a refrigerator for thawing. Jenkins and Tressler⁴⁴ reported losses from negligible to 20 per cent in six months at 0°F and much higher losses at 10 to 15°F, ranging from approximately 40 per cent to more than 90 per cent in various products. McIntosh and Tressler⁴⁵ found a variable loss of vitamin C up to 14 per cent in cooking a number of frozen vegetables for table use in various ways with from 13 to 30 per cent in the liquor and from 70 to 80 per cent in the solids, the amount in the liquid depending on the amount of cooking water.

It appears from these data and others that it is important not only to freeze vegetables quickly but

TABLE 4—*Extractive Effects of Blanching on Ascorbic Acid Content*

Time Minutes	Blanch		Ascorbic Acid Mg per 100 Gm Peas
	Temperature	Kind	
1	99°C	Water	21.0
2	99°C	Water	18.0
3	99°C	Water	17.0
1	99°C	Steam	18.8
3	88°C	Water	21.2
4	88°C	Water	23.2
6	88°C	Water	22.6
2	88°C	Water	8.1
4	88°C	Water	7.2
6	88°C	Water	9.1

to maintain a low storage temperature and to prevent thawing until such time as they are to be cooked for the table.

CANNING

Canning was the first method of preserving foods to receive scientific study. The latest report of the National Resources Planning Board states "No better example of the value to be obtained from a trade association's operation of its own technical research laboratory can be cited. The industry quickly availed itself of the association laboratory's findings and put its recommendations into effect in processing. The industry has benefited in many ways, the public has benefited through having made available a very wide variety of wholesome foods at lower costs." In another connection the report states "The production of vegetables suitable for canning has inspired some lines of important research." Agricultural experiment stations of many states have had a hand in developing varieties especially suitable for canning. Canning factories are located in the center or vicinity of the areas supplying them. Deterioration of raw produce due to storage is not a problem. Each crop may be harvested

when it is at its prime. No allowance need be made for ripening in transit, thus permitting full development on tree or vine.

The chief feature in canning foods is the application of sufficient heat to destroy spoilage organisms. This in many cases is more than is necessary for table use. One of the most notable effects is the change in green vegetables from a bright green to an olive green. This has been in part linked⁴⁶ to a lowering of the p_H value which generally occurs in cooking foods, the degree depending on the time and temperature. Since chlorophyll has never been found to possess nutritional functions nor the change in p_H to have any nutritional significance, these effects need not be discussed here.

Tinsen⁴⁷ has tabulated effects of cooking and canning. That processing is without effect on vitamin A is evidenced by the experiments of Steenblock and Boutwell,⁴⁸ who autoclaved yellow maize chard, carrots, sweet potatoes, squash and alfalfa for three hours at 250 F without affecting the vitamin A. This is no more severe than any canning process.

Arnold and Elvehjem⁴⁹ studied the effect of processing dog food meat in 1 pound cans. The following thiamine losses were noted in a process of two hours at 240 F: beef kidney 80 per cent, beet lung 75 per cent and beef spleen 70 per cent. Leg muscle in one hour and fifty minutes at 250 F lost 80 per cent. In a sample of "meat food product" which contained a small amount of grains, the following losses were noted: at 240 F in one hour 60 per cent, in one and one-half hours 67 per cent, in two hours 70 per cent, in one hour and fifty minutes at 250 F 80 per cent. An interesting feature of these data is that doubling the process time raised the destruction only from 60 to 70 per cent, yet the product received a more severe heat treatment during the second hour because a considerable part of the first hour was required for the heat to penetrate the material in the can. The necessary processing time for such a product lies between one and two hours. The p_H of these products was between 6 and 7, whereas that of vegetables is approximately one p_H unit lower and the stability toward heat is much greater at the lower p_H . With lower p_H and better heat penetration for most vegetables the process is correspondingly less severe. In the absence of direct data on the various vegetables it may be inferred that destruction of vitamin B₁ in general canning is no less than the losses cited.

Schlutz and Knott⁵⁰ tested four lots of milk by feeding experiments before and immediately after evaporation and canning and found respectively 34, 24, 21 and 20 per cent losses. One sample, which contained 80 international units per quart when first canned, contained 68 after two months' storage and 59 international units after four months. Two other samples which lost originally 20 and 21 per cent of their B₁ with eight months' storage lost an additional 37 and 42 per cent respectively.

The best evidence of the stability of vitamin C to the heat of canning is the fact, such as described with tomato

juice that many foods when heated with dehydroascorbic acid will actually reduce it to ascorbic acid. This explains many of the observations of McHenry and Graham⁵¹ and others that heating in the case of several vegetables, increased the titration value toward 2,6-dichlorophenolindophenol. Unsuccessful attempts have been made to explain such phenomena on the basis that ascorbic acid is in part held in some complex combination and this heating hydrolyzes it. Many foods when processed in the can actually have a higher titration value after the process. Doubling the commercial process of canned peas from twenty-five to fifty minutes at 250 F did not lower their value as an antiscorbutic for guinea pigs. Tomatoes⁵² and apples, although it was necessary to deplete the apples of oxygen by the so-called soaking process already referred to.

Perhaps the most significant data on the nutritional value of canned foods has been obtained in a number of experiments in which a diet entirely of canned foods was fed. While it may be said with whatever justification that human beings over many generations have adapted themselves to a cooked food diet, this cannot be said of rats and guinea pigs. Yet both species of animals, the rats over ten generations and the guinea pigs over seven, thrived better on a canned food diet than on a diet of similar foods uncooked, according to Kohman, Eddy, White and Sanborn.⁵³ Foods for these experiments were purchased in the New York City markets as they would be for family use.

Cooking of foods renders the calcium more available. The vitamin A of foods like peas and spinach has been found to be more readily available after cooking. Reference has already been made to such an effect on vitamin B₁ and riboflavin in various beans. The protein of all legumes is improved nutritively by being subjected to heat.

In France Chetel,⁵⁴ after feeding rats canned and noncanned foods over a period of fourteen generations, reported that when individuals of the two groups were put on a vitamin A-free diet at the Pasteur Institute those having been raised on canned foods showed the first symptoms of vitamin A deficiency two weeks later than those raised on noncanned foods.

Godden⁵⁵ in Great Britain fed, on a comparable basis (1) diamed canned foods, (2) tinned canned foods (solid and liquid) and (3) home cooked foods from which the cooking water was discarded. On a basis of reproduction, milk supply and growth, the first and last diets yielded comparable results but the canned food diet with the liquor included was unsatisfactory because of its bulkiness. This difficulty is in evidence only when too much of the diet is made up with foods with considerable liquid. The matter can readily be corrected by inclusion of higher caloric foods such as pork and beans, macaroni and cheese, and brown bread, all of which are readily available in canned form. Subsequently, Godden and Thomson⁵⁶ made many observations over several gener-

tions on canned and uncanned foods and found no basis for distinguishing between the two.

A word is in order regarding the containers for canned foods. Daniels and Rutherford⁵⁷ claim better vitamin preservation in tin than in glass. Fellers and Buck⁵⁸ point out that entrapped oxygen in commercially packed puffed peas, spinach and tomato juice may not disappear until twenty to sixty days after being packed in glass. Vitamin losses occurred mostly during this period and relatively little after six months. Glass covers for glass containers are of necessity dome shaped, and this inevitably entraps more air than the cover of the tin can. Commercial canning minimizes this entrapped air in glass canning by vacuum closure, which the home canners cannot employ.

It may be added that traces of entrapped air in tin cans disappear completely within twenty-four hours in a plain can but may persist for several days in an enameled can. This prompt disappearance of oxygen in a tin can is a consequence of the high reduction potential of the film of nascent hydrogen with which tin in contact with foods coats itself. This film is of great value both in furnishing a reducing atmosphere and in furnishing protection for the tin against the action of the food on it.

DEHYDRATION

Dehydration is limited largely to a few fruits—prunes, raisins, peaches, apples, apricots, figs, dates and the like. Vitamin C suffers almost complete destruction in most dehydrated products. The vitamin C protective effect of sulfuring (to prevent darkening of the light colored fruits) was shown by Morgan, Field and Nichols.⁵⁹ This same sulfuring process may, however, prove to be as destructive to vitamin B₁ as it is protective for vitamin C. When first sulfured, the fruits may contain sulfur dioxide from 2,500 to 10,000 parts per million. The splitting of thiamine into its thiazole and pyrimidine components by sulfur dioxide was the clue to its identification. The quantitative determination of thiamine by the microbiologic (yeast) method has as its basis the complete splitting of its molecule by sulfite. Treatment with sulfur dioxide is one means of preparing a vitamin B₁ free diet for experimental work.

Dehydration of vegetables, usually stimulated during wartime, has not met with a high degree of satisfaction as yet, so far as is reported. In most cases the flavor changes are too pronounced. Rancid and haylike flavors commonly develop. Dehydration of eggs and of milk, particularly skim milk, is proving very useful, and according to recent reports this is true also of lean meat. Since moisture free butter fat stores well, it makes possible, with dehydrated skim milk, to have reconstituted milk suitable for many purposes. While the nutritive value of dehydrated vegetables for food for human beings seems not to have been given especial attention, some deductions may be made. Fraps and Kemmerer⁶⁰ found that when fish oils are mixed with poultry feed from 79 to 100 per cent of the vitamin A is lost within a month. Taylor and Russell⁶¹ state that

dried and chopped alfalfa hay stored in a bag lost 50 per cent of its carotene content in three months and the remaining carotene became less potent. In this connection it is interesting to note that even in raw carrots a tenfold variation in carotene and depth of color has been accompanied by little more than a twofold variation in vitamin A potency. It is thus possible that dehydrated vegetables retain their vitamin A values but poorly, and there is ample evidence that vitamin C is almost completely lost. In recent developments, vegetables are being blanched before dehydration. It is still problematic what will be the effect of the blanch.

MISCELLANEOUS PROCESSES

The distinctly inferior nutritive value of bleached vegetables is not commonly realized. Plant breeding has produced firmer heads of lettuce and cabbage and less green on celery, but Crist and Dye⁶² have pointed out that the green outer leaves are many times richer not only in vitamin A but also in nearly all the mineral elements. They are known to be richer in vitamin C also and probably in other vitamins as well. It is fortunate, therefore, that in recent years green asparagus for canning has become more popular.

The legal standards for jellies, jams and preserves demand a minimum of 45 pounds of fruit to 55 pounds of sugar. The final product must have a minimum of 65 per cent solids in the case of certain fruits and 68 per cent in others. This makes it necessary to evaporate about 10 per cent of the water in the fruit in the process of making conserves. In commercial practice this requires a relatively short time and ascorbic acid losses may be 10 to 15 per cent, and under vacuum even less. There is some evidence that the sugar has a stabilizing effect on ascorbic acid. Further than this little information on nutritive value is available except that the high sugar content makes the caloric value of conserves overshadow other nutrients. From various foreign countries come reports of the importance of conserves in this emergency as vitamin C sources by making possible the utilization of heretofore little used items, chief of which are rose hips. Not all rose hips are rich in vitamin C, however. Some contain only a few milligrams of ascorbic acid per hundred grams; some are equal to and others several times as rich as tomatoes.

Spoilage is prevented in dehydrated foods because they lack the water necessary for micro-organisms. In conserves the high sugar content makes the water unavailable by osmosis. Because of its smaller molecule, much smaller percentages of sodium chloride will preserve foods, but in removing excess salt soluble food constituents are removed.

The hydrogenation process has made available for human consumption much vegetable fat. From the work of Hoagland and Snider⁶³ and of Sherman⁶⁴ it is to be inferred that hydrogenation lowers the digestive coefficient and that the loss of unsaturation causes inferiority as respects other nutritive phases. That this is of any practical dietary significance is not known.

Ethylene treatment of fruits is not believed to influence any nutritional quality. It merely hastens processes already taking place.

The baking of bread is said by Hoffman Schweitzer and Dalby⁶ to result in a loss of from 5 to 9 per cent of the thiamine content. This loss occurs largely in the crust. Toasting causes another loss, ranging from 12 to 24 per cent.

There is no evidence that fermentation, as occurs in the making of sauerkraut, in pickling or in wine making, has a specific effect on any of the vitamins nor are the vitamins in any fermented product any less subject to adverse conditions than they are in the unfermented

CONCLUSIONS

Modern methods of food distribution supply us with vegetables and fruits of numerous varieties in many forms. Vegetation extracts minerals from the earth, usually in suitable proportions, and synthesizes our vitamin supply. Until subjected to heat, fruit and vegetables are live tissue and as such constantly undergo changes some of which are detrimental. Methods have been devised to limit such changes, but whether it is for storage, frozen, dehydrated or canned foods, there still remains work to be done to ascertain more definitely the extent of changes that take place for each type of commodity under the various conditions to which it may be subjected and to find ways of minimizing still further undesirable changes. It is obvious even now that to use vegetables and fruits generously in our diets is in accord with our aims in nutrition today.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION FOR THE VALUABLE ASSISTANCE RENDERED IN THE PREPARATION OF THIS REPORT BY DR. GEORGE M. COATES, EDWIN P. FOWLER, W. E. GROVE, WALTER HUGHSON, ISAAC H. JONES, DEAN M. LIERLE, DOUGLAS MACFARLAN, C. STEWART NASH, HORACE NEWHART, PAUL E. SABINE AND BURT R. SHURLY. HOWARD A. CARTER, Secretary

MINIMUM REQUIREMENTS FOR ACCEPTABLE AUDIOMETERS¹

1. Audiometers shall produce vibrations at frequencies within hearing range (approximately 128 to at least 8192 cycles per second).

(a) They shall be equipped for testing both air and bone conduction.

2. Frequencies. (a) Fixed or continuous frequencies from 128 to 8192 cycles per second. If discrete frequency steps are provided, the tones shall be 128, 256, 512, 1024, 2048, 4096, 8192 cycles per second. Numerical annotations to be used to designate pitch.

(b) The frequency of any test tone shall remain within ± 5 per cent of the designated value under the manufacturer's specified or indicated operating conditions. Dials shall be marked so that frequencies may be identified readily.

3. Attenuation. Audiometers shall be calibrated in decibels with 5 decibels per step or less. In no case should more than 5 decibel steps integral be used. Tolerant limits are to be within $\pm 1\frac{1}{2}$ decibels per 5 decibel steps and ± 5 decibels cumulative at any portion of the intensity range calibrated in a room free from extraneous noises. Dials shall be easily read. The term 'percentage hearing' shall not be used on dial or charts. Hearing losses shall be reported in decibels units loss.

6. Hoffman, Charles, Schweitzer, T. R. and Dalby, Gaston. The Loss of Thiamine in Bread in Baking and Toasting. Cereal Chemistry 17: 737 (Nov.) 1940.

1. A clinical audiometer is an instrument for measuring the acuity and range of hearing.

4. Range of intensity (air conduction only). The intensity range of the test tones above the normal threshold shall be at least that as follows:

Test Tone Cycles per Second	Intensity Range Decibels
128	60
256	80
512	85
1024	90
2048	90
4096	90
8192	70

5. Wave form. The purity of tone in the air conduction receiver shall be such that the harmonics at any particular frequency shall be at a level not less than 25 decibels as measured on the closed coupler artificial ear of from 4 to 5 cc. in volume except for discrete frequency of 128 the harmonics shall be at a level not less than 20 decibels.

6. Extraneous noises. (a) The level above threshold of the sound (for normal hearing people) caused by line noises (hum and commutator ripple) and all other instrument noises shall be at least 60 decibels below the level of the test tone for frequencies of 1024 cycles per second and higher frequencies, and at least 40 decibels below the level of the test tone for frequencies below 1024 cycles per second.

(b) A bone conduction receiver shall be so constructed that it does not produce sound in the air to such an extent that the sound reaching the tympanum through the auditory meatus could influence the validity of the bone conduction measurement. When the bone conduction receiver is placed in approximately the same position as is used in testing bone conduction but is held just off the head instead of in contact the level of the sound reaching the tympanum shall be at all frequencies at least 5 decibels below the level which the receiver generates by bone conduction when in contact with the head as judged by a normal ear.

7. Power supply. This is to be either alternating or direct current or battery.

8. Ruggedness of construction. Audiometers shall stand reasonable usage. Employment of readily obtainable and replaceable parts is required.

9. Uniformity in calibration. Audiometers shall be calibrated thus: Intensity in decibels and frequency in number of vibrations per second.

10. Standard for reference normal threshold by air conduction for audiometers for general diagnostic purposes. The standard for reference normal threshold by air conduction for audiometers for general diagnostic purposes shall be as given by the average voltage across three standard receivers maintained at the National Bureau of Standards and determined by transfer measurements from Western Electric 552 Receivers of 2A Audiometers and representing the reference normal threshold given by the U. S. Public Health Service 1936 National Health Survey.

Frequency of Test Tone (Cycles per Second)	Standard for Reference Normal Threshold by Air Conduction as Given by Average Voltage Across Three Standard Receivers (Decibels from 1 Volt)
128	-73.0
256	-88.0
512	-102.0
1024	-109.0
2048	-111.5
4096	-107.0
8192	-75.0

11. Audiogram or auditory chart. An audiogram blank shall use the same base line for bone conduction results as for air conduction results. The chart shall be as simple as possible. The coordinates of the charts shall be some appropriate number

of decibels and octaves or fractions of an octave. In order that the chart may present a suitable visual impression there shall be a ratio of 1 to 2 between the dimension of a 10 decibel step and that of an octave step.

12 Definition of threshold of hearing. The American Tentative Standard Acoustical Terminology defines the normal threshold of audibility as the modal value of the threshold of audibility of a large number of normal ears of persons in the age group from 18 to 30 years. For purposes of recording, the threshold of audibility at any frequency is the audiometer setting corresponding to the lowest intensity at which the person being tested indicates that he hears the tone more than half of the number of times that it is presented to him.

13 The manufacturer shall guarantee in writing

(1) that one year from date of purchase the manufacturer will recondition and put in acceptable operating condition at no cost to the purchaser, other than transportation charges any audiometer of his manufacture that may develop defects except when such defects are due to improper care or accident,

(2) that at any time within five years from date of purchase the manufacturer will rebuild at a reasonable cost or replace parts necessary to bring an audiometer of his make to a satisfactory working condition,

(3) that the maker will provide adequate instructions for the proper care and upkeep of his products and will encourage the purchaser to send his audiometer at reasonable intervals to the factory or to a qualified distributor for check as to performance and needed servicing at a reasonable cost.

14 Marketing and advertising. Rules of the Council on Physical Therapy shall be adhered to by manufacturers of acceptable audiometers.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

HOWARD A. CARTER, Secretary

MAICO HEARING AID, MODEL 42, ACCEPTABLE

Manufacturer: The Maico Company, Inc., 2632-2636 Nicollet Avenue, Minneapolis

The Maico Hearing Aid, Model 42, consists of a combined microphone and vacuum tube amplifier unit contained in a molded case $4\frac{1}{2}$ by $2\frac{1}{2}$ by 1 inches, weight $4\frac{9}{10}$ ounces, and A and B battery unit in leather case $4\frac{1}{2}$ by $3\frac{3}{4}$ by $1\frac{1}{4}$ inches, weight $12\frac{1}{2}$ ounces, and crystal receiver $\frac{3}{16}$ by 1 inch in diameter.

Maico Hearing Aid Model 42

BATTERIES

A feature of the instrument is a plug resistor which can be inserted in the circuit between the A and B batteries, serving to reduce the A battery current when new batteries are in use. Its removal, as the battery grows old, should appreciably increase usable battery life, voltages and currents. The voltages and current drains are

		Voltage	Current
A battery	Maico Extra Life #499	1.5 without resistor	105 milliamperes
		1.3 with resistor	97 milliamperes
B battery	Maico B 941	.33	1.3 milliamperes

ACOUSTICAL GAIN

All measurements were made with the A battery resistor in the circuit. The acoustical gains at various frequencies are

	128	256	512-3072	4096
Full volume	Nil	?	36-33	14 decibels

The instrument has a single volume control. Tests confirmed the manufacturer's claims to a reasonable degree for automatic volume control, allowing for a full volume setting of the instru-

ment without excessive amplification of loud sound. The internal noise level is low, and the instrument is electrically stable and, with a reasonably well fitted earpiece, is free from acoustical feedback when turned up to full volume. The screw adjustment on the back of the instrument was supplied with only screw number 3 in, and all tests were made with this adjustment. There are two types of instruments, so called 'one dot' and 'two dot'.

ARTICULATION TESTS

The usual syllable and sentence lists were used with hard of hearing subjects at a distance of 5 feet and showed satisfactory performance.

The instrument is well made. Cords are reinforced with neoprene casings at connections, and mechanical details are well designed. The manufacturer states that a battery adapter can be supplied to allow the use of a large number of makes and types of batteries.

The Council voted to accept the Maico Hearing Aid Model 42, for inclusion on its list of accepted devices.

ACOUSTICON, MODEL A-55, ACCEPTABLE

Manufacturer: Dictograph Sales Corporation, 580 Fifth Avenue, New York

The Acousticon Model A-55 a vacuum tube hearing aid was examined by the Council on Physical Therapy. Following are the results of that investigation.

The instrument was found to consist of a combined microphone and amplifier unit in a molded case $3\frac{3}{4}$ inches by $2\frac{1}{4}$ inches by $\frac{3}{4}$ inch, weight $3\frac{9}{10}$ ounces, air receiver $\frac{7}{8}$ inch diameter, $\frac{1}{2}$ inch thick and bone receiver. The battery unit is $3\frac{5}{8}$ inches by $3\frac{3}{8}$ inches by $1\frac{1}{4}$ inches weight $11\frac{9}{10}$ ounces.

BATTERIES

Voltages and current drains, with instrument turned full on, were

A Battery	Acousticon No 30	1.5 volts	80 milliamperes
B Battery	Acousticon No 51	30 volts	1.4 to 1.8 80 milliamperes
C Bns		3.0 volts	

ACOUSTICAL GAIN

The instrument has a single volume control and a screw adjustment on the back of the case. Three positions of the latter are indicated by the letters L, M and H. So far as could be ascertained without extensive response measurements, the effect of turning this screw from the H to the L position was to increase the low frequency amplification without materially affecting the high frequency gain. There was only slight difference between the M and L settings at the frequencies at which amplification measurements were made. The internal noise level was low, and the instrument was not unduly sensitive to mechanical shocks. With a well fitting earpiece the volume control could be turned full on without acoustical feedback. The order of magnitude of the acoustical gains were

Screw Setting	128	256	512-2048	3072	4096
H	Nil	?	25-41	43	15.5 decibels
M	Nil	19	30-45	45	16.0 decibels
L	Nil	16	25-41	36	19.0 decibels

Whispered voice was understood at a distance of 5 feet by a hard of hearing subject with an average hearing loss of 45 decibels in the speech range.

ARTICULATION TESTS

The usual articulation test with hard of hearing subjects using both the bone and air receivers showed satisfactory performance.

The Council voted to accept the Acousticon, Model A-55, for inclusion in its list of accepted devices.

THE PEPPER HEARINGS ON MEDICAL MANPOWER

The Procurement and Assignment Service for Physicians, Dentists and Veterinarians established as a part of the War Manpower Commission, is carrying on a scientific, carefully considered allocation of physicians, dentists and veterinarians to meet the needs of the armed forces, industry and the civilian population, as directed by the President of the United States in his order establishing this body. Nevertheless, a small group of individuals, including a few physicians apparently dissatisfied with actions of the Procurement and Assignment Service in some instances, was mustered to appear before a subcommittee of the Committee on Education and Labor of the United States Senate for hearings now being held in Washington. The American Medical Association was represented only on its own request. Obviously the American press has not been able to reflect fully the various facets of what some newspaper men have described as a "one man inquisition" conducted by Senator Pepper. *THE JOURNAL* hopes in future issues to print a rather full account of the hearings. Physicians may then judge for themselves the nature of the inquiry and the end apparently sought.

One of the chief facets thus far obvious is the desire of some industrial leaders and of the full time staffs of physicians which they employ to maintain their individual empires without disturbance regardless of the needs of the armed forces for physicians. They believe apparently that individual physicians should be taken by the armed forces before clinics, private hospital staffs, industrial organizations or similar groups are in any way disturbed. The first objective of the nation is the winning of the war. The armed forces require preferably physicians under 40 years of age. The decision as to who is physically fit or unfit for military service and as to who is 'essential' or 'not essential' cannot

be left to the opinion of the individual physician himself or to the organization which employs him.

The statements of Dr. Frank H. Lahey, chairman of the board, and of Dr. Max E. Lapham, director of the Procurement and Assignment Service, placed clearly before the Pepper "inquisition" the facts regarding the number of physicians in the United States, their availability for various types of service, the procedures that are being followed in protecting industry and civilian communities against a shortage of medical manpower, and the absolute impartiality with which the affairs of the Procurement and Assignment Service are being administered. Some witnesses tried to force the concept that the personnel of the Procurement and Assignment Service with all its widespread organization throughout the nation including the corps area boards and the state and county officials, all of whom contribute their services without remuneration, are creatures of the officials of the American Medical Association. Some representatives were charged with utilizing their positions to interfere seriously with the orderly functioning of American medical practice and indeed to injure the public health. The concept is itself as false as many of the other insinuations that were made by some of those who testified. This will be clear to every physician who studies this testimony when it is printed.

Prime movers in this assault on the Procurement and Assignment Service and perhaps also on the War Manpower Commission of which it is a part are, as will be obvious from the testimony, Paul de Kruif, Ph.D., Michael M. Davis, Ph.D., Mr. Henry J. Kaiser, eminent industrialist, the head of his medical services, Dr. Sidney Garfield and two physicians who are said to have been heard in executive sessions of the committee and whose names are thus far not available. Accompanying Senator Pepper in his conduct of the "inquisition" are two economists, most of whose questions, as will also be clear in the published testimony, are directed toward establishing the view that American medicine has failed to meet its obligations in the war effort and that some agency must be established with totalitarian control over all medical facilities.

In his testimony before the hearings, Dr. Thomas Parran of the U. S. Public Health Service spoke strongly in behalf of the services being given by the medical profession in this time of the nation's need and stated without the slightest equivocation:

SENATOR PEPPER: Do you think that allocation of medical personnel between military services and civilian work should have been handled through the Public Health Service rather than through the Procurement and Assignment Service?

DR. PARRAN: I think the present arrangement is the best. As a matter of fact, after seeing the system as it was set up in Great Britain eighteen months ago, I discussed that system with the Health and Medical Committee and others and

perhaps was responsible to some extent for a separate group representing the medical and dental professions being set up to deal with this problem

Nevertheless, 'Ph D's' de Kruif and Davis do not hesitate to endeavor to force on the U S Public Health Service a responsibility which the Surgeon General of that service certainly does not seek and which is opposed to his own statement based on serious study and established knowledge, that he considers the present method best"

Already evidence has been submitted that the services established by Mr Henry J Kaiser, under the direction of Dr Sidney Garfield, are endeavoring to hold from the armed forces even the opportunity to determine for themselves whether or not the considerable number of young men employed on salaries by this industrial organization are fit and available for military service. Certainly the decision as to whether or not these young men may best serve the nation in time of war in the armed forces or in the civilian capacities which they now occupy cannot be left to their employers. The final responsibility does not rest on the Procurement and Assignment Service, which can only indicate its belief as to whether or not such men are essential. The decision rests—and wisely—with the local boards in the areas concerned, these boards may give consideration to the recommendations made by the Procurement and Assignment Service. From the decisions of the local Selective Service boards appeal may be made, according to conditions established by our government, even as high as the national agencies in Washington or the President himself. Every young physician in the United States under 40 years of age should now determine in his own heart and in the light of the principles of public service traditional in medicine, whether or not he is doing his utmost to serve the nation in this time of emergency.

When the transcript of the hearings is published in forthcoming issues of THE JOURNAL, readers may determine the extent to which the hearings conducted by Senator Claude Pepper of Florida represent a courteous effort on the part of a public official to determine the facts, so that representatives of the people may legislate wisely to meet the needs of the hour, or whether or not a public agency, namely a senatorial hearing, is being used—or abused—under the leadership of a senator, to pillory a profession. Already that profession has contributed to the armed forces more than forty thousand physicians, the very best that the nation can supply. The remainder are working without thought of hours, of exposure, of fatigue or of recompense to maintain medical service for the American people in this time of trial. The performance

displayed in Senator Pepper's hearings is not likely to improve the morale of American medicine at the very time when it should be at its highest in the service of the war effort

PRONENESS TO ACCIDENT

Recent studies made by the Industrial Health Research Board of the Medical Research Council of Great Britain¹ add further convincing evidence that some individuals in a working group are more liable to accidents than others in the same circumstances, they may be designated as "accident prone." Various general conditions of work and environment have been recognized as contributory causative factors affecting the incidence of accidents, such as hours, speed and type of work, experience, age and fitness of workers, heating, ventilation, lighting and other working conditions, and attitudes of workers and management. In addition to these general factors it is evident that an important specific factor of "accident proneness" may be present in certain individuals. Such persons apparently have a special liability to be the subject of accidents just as some are particularly susceptible to certain diseases. Not only may a small percentage of a working group show a high percentage of the total sickness disability in the entire group, it has been found that as little as 10 per cent of a group may be responsible for as much as 75 per cent of the accidents occurring among them.

Accident proneness may be an innate characteristic of some people and a personal phenomenon independent of any question of responsibility, conscious action or blameworthiness. Those who sustain an undue number of one kind of accident also sustain an undue number of other kinds. Accident proneness is a relatively stable quality obeying fairly definite laws. Moreover, those who are most often ill tend, on the whole, most often to have accidents, indicating that the prevention of accidents may depend to a considerable degree on the prevention of sickness and emphasizing further the need for greater attention to the industrial health program as a whole.

According to the British studies, accident proneness may be measured to a certain extent by tests involving rapid and accurate coordination of hand and eye and by linguistic intelligence and mechanical aptitude tests. Admittedly, all such tests are as yet in the experimental stage and their validity at present appears much greater among skilled workers than in unskilled occupations. A second suggested method of predicting the "accident prone" is by determining the number of accidents sustained by each individual in a working group during

¹ Industrial Health Research Board. Emergency Report No. 3. The Personal Factor in Accidents. Sept. 3, 1942. London. H. M. Stationery Office.

a previous period of exposure. This method has certain disadvantages, particularly from the points of view of the delay in time or waiting period involved and the present inadequacy of accident records as a whole. The latter fact emphasizes the great need for better records of accidents. A combination of these methods of testing probably is the most effective way of using our knowledge of accident proneness to reduce the incidence of accidents.

As indicated in the British report, there is no question of not employing those who are accident prone. They are fairly normal persons and can be usefully engaged in most occupations. It is only if they are employed in an occupation with a high accident liability that they are a danger to themselves and to others. Bristol² has indicated that, while it appears reasonable that a person should be removed from a position in which he is a potential danger to himself and others, industries which realize their obligations to society in general undoubtedly will be slow to penalize an individual because, through no fault of his own, his mental and physical qualities are not equivalent to those of fellow employees. The chief objective should be to see that these accident prone individuals are identified through medical and other examinations and are assigned to work in which the severity and danger of their potential accidents are reduced to a minimum.

Current Comment

AMERICAN ATABRINE

The most prevalent disease afflicting the populations of the world is undoubtedly malaria. How many cases occur each year is not known, but estimates place the number as high as 800,000,000. In local areas, particularly in the United States and Panama, drainage and sanitary engineering projects have had some influence on the incidence of malaria, but such measures cannot cope with the disease on a worldwide basis. Until 1932 the populations of the world were principally dependent on quinine and its derivatives for protection against the malady. With the discovery of Atabrine in 1932 a new and potent addition to the antimalarial armamentarium made its appearance. When the Netherlands East Indies fell to Japan, the source of practically the entire world supply of quinine was lost to the United Nations. Atabrine, now officially recognized under the nonproprietary name quinacrine, assumed a role of unsurpassed importance as a strategic drug. Although it was originally prepared in this country from imported intermediates, in 1941 American chemists solved the problem of synthesizing the drug through intricate steps. The question has been raised whether the American Atabrine is identical in all respects with the German drug. This question was studied as a war project by the Division of Chemistry and Chemical Technology

of the National Research Council. Extensive chemical, pharmacologic and clinical investigations were made in leading institutions throughout the country. The report released by the National Research Council establishes the fact that there is no longer reason to doubt that the drug manufactured in this country is genuine, comparable in every respect with that produced in other countries.

"ETHYLENE DISULPHONATE" LAUNCHED AS A CURE FOR ASTHMA

Inquiries concerning a "new" treatment for asthma which employs injections of "ethylene disulphonate" appear to have been stimulated recently by publicity in *Newsweek* for October 12 and by the United Press in various newspapers. A paper given by Dr Norman M. Smith of Minneapolis at the Mississippi Valley Medical Society meeting in Quincy, Ill., was the basis for the publicity. "Ethylene disulphonate" was originally promoted under the name Allergosil by the Spicer-Gerhart Company of Sunland, Calif. Back of this company is one Edward H. Spicer, who some years ago was actively connected with a product called Edwenil. Allergosil is not available for interstate distribution but "for investigational use only" under the provisions of the Food, Drug and Cosmetic Act of 1938 controlling the release of new remedies. Request from outside California, addressed to the Spicer-Gerhart Company, indicates that this preparation, which is described as a 1:10 dilution of "ethylene disulphonate," can be obtained for investigational purposes at a cost to the profession of \$13.50 per single 2 cc dose. Here is another example of hasty and inadvised publicity based on scanty scientific evidence and questionable promotional practice.

HEALTH SUPPLEMENTS

Many newspapers have during recent years published supplements on health. A special supplement recently prepared by the Public Relations Committee of the Philadelphia County Medical Society for the *Philadelphia Record* of October 27 deals with the "Care of Health and First Aid in Pictures." This supplement of twenty pages shows in a series of strips most of the procedures now recognized as competent in first aid, also some excellent pages on nutrition, care of the teeth, the common cold, safety first and industrial efficiency. The leading industries of Philadelphia cooperated in paying for space, and all of the companies which have industrial medical departments approved by recognized agencies aided in the publication. They went on record as favoring examination of the individual previous to employment, proper guards on machinery, proper control of plant environment, and a physician in charge of the medical department with proper personnel and equipment to give attention to all injuries or illnesses. The Public Relations Committee of the Philadelphia County Medical Society rendered a great service to the people of Philadelphia in aiding in the production, authentication and publication of this supplement.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

THE PRESENT ROLE OF THE ANESTHESIOLOGIST IN THE ARMY

STEVENS J MARTIN, Ph D, M D

Major M C U S Army Chief of Sections on Anesthesia and
Operating Pavilion Resuscitation and Oxygen Therapy
Tilton General Hospital

Fort Dix, New Jersey

The anesthesiologist has played a significant part in the history of military surgery. Always mindful of his prime obligation to his patient and his surgeon, he was hindered in his early development by the scarcity of recognized anesthetic agents and technics and by the appalling lack of basic principles to guide his clinical judgment. What recognition he did receive expressed, in small measure, the growing need and respect for his services. The nineteenth century with its American Civil War¹ and various British colonial campaigns² saw the wave of enthusiasm for chloroform inhalation anesthesia. The opening of the present century marked the increasing popularity of ether³ and the introduction of spinal subdural technics⁴. During World War I there appeared, in addition, the use of local infiltration anesthesia⁵ and nitrous oxide-oxygen⁶ and ethyl chloride inhalation anesthesia. Other developments of military anesthesia have been reviewed in more detail in a recent publication⁷. Although the anesthetist had become of greater service to his medical unit in World War I, the rank of an officer was not officially authorized. This was rightfully so, for anesthesiology was still in its infancy. It was apparently felt that knowledge of a few technics could hardly justify the respect of a medical specialist in the armed forces.

The aftermath of the last war, however, brought to light the fruitful experiences of military anesthetists. Perhaps the most significant of these was the teaching

outline of "signs of anesthesia" published by Guedel⁸. This contribution can truthfully be regarded as the first significant attempt to emphasize and evaluate the changing physiology of an anesthetized patient. Flagg,⁹ Gwathmey¹⁰ and others tried to popularize various procedures used by them while in the Army. Waters introduced the clinical use of the carbon dioxide absorption technic¹¹ and cyclopropane anesthesia¹². Meanwhile, other anesthetists reported their gratifying results with intravenous anesthesia,¹³ regional anesthesia,¹⁴ and significant modifications of spinal anesthesia¹⁵.

Rapid advances, both in the clinic and in the laboratory, served to establish anesthesiology as a science and medical specialty. Universities¹⁶ and other civilian institutions¹⁷ incorporated anesthesiology in their organization as a separate department. Recognition by the American Medical Association¹⁸ paved the way for the formation of the American Board of Anesthesiology with its powers to certify specialists. A few years ago a special section¹⁹ for anesthesia and operating pavilion was created in the organization of the surgical service of an army general or station hospital. Today, at long last and only after anesthesiology has been recognized wholeheartedly by official civilian and military medical groups, the trained anesthetist in the armed forces has been given the status of an officer. As such, the anesthesiologist is in charge of the Section on Anesthesia and Operating Pavilion.

FUNCTIONS PERFORMED

The present anesthesiologist in army general hospitals has fully justified his indispensable position. His duties are numerous and available twenty-four hours a day and encompass not only anesthesia but also supervision of the operating pavilion. Broadly speaking, his prime function is to schedule, coordinate and facilitate the operative procedures of the various surgical

hospital. As a part of the surgical department, he is responsible directly to the chief of the surgical service.

The accompanying tabulation outlines the duties of the present day recognized military anesthesiologist, more particularly those of a chief of Section of Anesthesia in a named general hospital of the Army. These will vary in scope somewhat in smaller medical units according to the type of hospital (station, evacuation, and so on) as well as its location and personnel.

Experience has borne out the fact that the functions of the anesthesiologist require the delicate, prompt and tactful integration of (1) administrative, (2) professional and (3) miscellaneous duties. Among the many administrative activities may be listed those referable

to personnel, supplies, inventory, repair and construction, reports and committee meetings. Personnel, consisting of duty and Medical Department Replacement Pool (MDRP) officers, nurses, enlisted men and civilians, must be trained and supervised until optimum proficiency is obtained. Aside from a few "key" individuals, members of the section trained in anesthesia or surgical techniques must be made available for transfer to combat units or to serve as a nucleus for another training center. In short one has an evanescent staff with an endless number of students.

Standard supplies must always be on hand in adequate amounts and not in excess. In the past certain items of a nonstandard nature have been requisitioned to facilitate various surgical specialties. The section chief is personally responsible for all furniture, surgical and anesthetic equipment issued to him by the medical supply officer. This often exceeds a financial responsibility of \$100,000. Hence, care in the proper use of the equipment must be emphasized and defective instruments must be repaired or returned for salvage. Experience has taught that personal supervision of the monthly inventory of equipment is the only safe and certain procedure to detect shortages and/or excesses. Repair of furniture, walls and halls, the construction of racks, cabinets and shelves or the installation of new equipment must be personally attended to and checked to avoid errors, delays and confusion. Monthly and annual reports are made out in detail to summarize the work of the section for the chief of the surgical service.

Efficiency reports of each member of the staff are often called for, particularly of MDRP officers. Occasionally, statements are requested for special investigations or to help evaluate or condemn unsatisfactory batches of commercially prepared drugs. From time to time it becomes the administrative duty of the section chief to attend certain closed interdepartmental staff meetings for consultation, organization or training purposes. On the whole, the administrative duties of the section chief of anesthesia are numerous, time consuming and quite different from those of the average civilian anesthetist.

Surprising to many, the professional duties of a military chief anesthetist are even more diversified than his administrative ones. He prepares or supervises the preparation of daily operative schedules of all major and minor surgery. Certain days and operating rooms are set aside for the various surgical procedures and specialties. About 3 p. m. of the day preceding, the ward officers hand in their individual surgical schedules, which are arranged into final form for the next day's work. The operating pavilion with its rotating staff is made available for any emergency twenty-four hours a day. Aside from preparing surgical schedules, it is the duty of the section chief to arrange for the sterilization or autoclaving of all surgical equipment and linen coming from surgical and medical wards as well as from the operating pavilion. This is a tremendous job and of a highly responsible and technical nature. Admittedly the details of this task are foreign to the average anesthetist, and hence they are commonly relegated, in large measure, to an adequately trained dependable nurse. However, although she may supervise such work and train enlisted men to aid her, the full responsibilities of her duties rest on the shoulders of the section chief.

Referable to anesthesia, per se, the duties of the military anesthetist in an army general hospital are

²⁰ Hospital Regulations. Tilton General Hospital. Fort Dix, New Jersey, 1941.

essentially similar to those in civilian institutions. He administers recognized anesthetic agents such as ether, nitrous oxide, methylene, cyclopropane¹ and sodium pentothal and also uses the accepted inhalation, spinal, intravenous and block techniques. In addition, he supervises the clinical anesthesia done by his staff, then preoperative and postoperative rounds and the recognition and treatment of postanesthetic respiratory and circulatory complications. He is often called on to discuss case presentations before the hospital staff or deliver lectures to them of general interest. Formal instruction, however, in the nature of an intensive course in anesthesiology²² is confined to selected duty and MDRP officers, enlisted men and occasionally a nurse. Clinical anesthetic problems of military nature have presented themselves from time to time and have stimulated research. Although their study has been pursued, their completion has been admittedly slow and difficult.

The military anesthetist in some hospital units is in charge of all inhalation²³ and fluid therapy. While such an added task can be burdensome, its rightful and centralized control by an anesthetist has its academic and practical virtues. Such a procedure is not unlike that followed in civilian hospitals and at Tilton General Hospital has thus far proved to be valuable in the proper safeguard of the welfare of our patients. It has been the duty of the anesthetist to administer or supervise the administration of oxygen, carbon dioxide or helium therapy of surgical, medical or dental patients. Whole blood transfusions as well as the actual preparation of isotonic solution of sodium chloride with or without dextrose are also supervised by the section chief of anesthesia. Dried and liquid plasma and commercially prepared isotonic solution of sodium chloride are dispensed by the anesthetists only on request of the ward officers.

The functions of a military anesthetist are not limited to administrative and professional duties alone. In hospitals where officer personnel is inadequate in number and/or in proper training the anesthetist may be and has been called on to assume miscellaneous duties. This may include those of a section chief of physical therapy, an assistant surgical ward officer or a member of various boards. At different times of the year he must attend classes for basic training in the lecture room or out on the drill field. He may be assigned to other nonmedical duties. This has been true particularly in evacuation and other smaller hospital units where the surgical activity, in amount and variety, may be dormant for variable periods of time. To be sure, his life is never dull but is profitably and well occupied.

COMMENT

The role of the anesthesiologist in the Army at the present time is admittedly significant and far more different from that of military medical units of World War I or of modern civilian hospitals. Whereas in the past he was merely a technician, or noncommissioned officer at best and without much responsibility, he is

now significantly in control of the operating pavilion or what may be regarded logically as the center of activity of the surgical service.

While the administrative, professional and miscellaneous duties of the military anesthetist are admittedly numerous as compared to civilian anesthesiologists, his responsibilities do not end here. To facilitate all his duties, he has a major problem of "paper work" to reckon with. In accordance with Army Regulations this phase of his work cannot be slighted and receives no less attention than his dutiful regard for anesthesia records. In addition it must always be remembered that the section chief of anesthesia now is an officer, a cherished position governed by army tradition and subject to regulations applying to officers of all arms and services.

The crying need for military anesthetists is occasioned not solely by the relatively small number reporting for active duty but particularly by the growing appreciation of the service they can provide to safeguard the welfare of patients. The Army is cognizant of the value of their academic and clinical background and is becoming "anesthesia conscious." It now remains for anesthesiologists to nurture and maintain this most wholesome and recent recognition by affording the safest and most adequate anesthesia to military patients. This should be regarded by anesthesiologists still in civilian clothes not as an invitation but as a challenge to do their share for their specialty and particularly the armed forces.

SUMMARY

The anesthesiologist in the Army has earned his status of an officer. His many and diversified duties, as compared to those of a civilian anesthetist, have made him indispensable to the proper functioning of army hospitals. It remains for the future to determine the rationale of the confidence the Army has put in the present day anesthesiologist.

CHEMICAL WARFARE SERVICE

The new commandant of the Chemical Warfare School at Edgewood Arsenal, Maryland, is Brig Gen Alexander Wilson, formerly chief of the Field Division of the Office of the Chief of Chemical Warfare Service. Col Patrick F Powers has been appointed to succeed Col Harry A Kuhn as chief of the New York Chemical Warfare Procurement District. Colonel Kuhn has been made chief of the Control Branch of the Office of the Chief of Chemical Warfare Service in Washington. Col Adrian St John who recently received the award of the Purple Heart for heroism in Burma has reported for duty in the office of the chief. At the invitation of the government of Mexico, officers from the Civilian Protection School at Texas A & M College recently went to Monterey, Mexico, to give instructions and demonstrations in chemical warfare under the direction of Lieut Col Harold R Brayton. One thousand persons took the special course of instruction and many more thousands witnessed the chemical warfare demonstrations.

ARMY MEDICAL PERSONALS

Col Harry R Berry has assumed duty as hospital inspector at Letterman General Hospital San Francisco, and Lieut Col Harold I Amory, chief of the radiologic service at Letterman General Hospital, has been ordered to new and undisclosed duties—Lieut Col Francis M B Schramm has assumed command of the station hospital at Camp Pickett, Virginia, succeeding Col Frank T Hallam—Majors Carson F Hunt, Arthur F Dorner, Millard E Gump and Capt Donald D Meyer have been ordered to Luke Field, Arizona.

NAVY

DR IVY TO DIRECT NAVY
RESEARCH INSTITUTE

The new Naval Medical Research Institute at Bethesda, Md., was placed in commission on October 27. Among those attending the ceremonies were Rear Adm. Ross T. McIntire, surgeon general of the navy and Rear Adm. Harold W. Smith, chief of the Division of Research. The institute will be concerned chiefly with the physical and mental conditions of aviators, submarine crewmen and marines. The scientific director of the new medical unit is Dr. A. C. Ivy, professor of physiology, Northwestern University Medical School, Chicago, who is now on leave of absence from the university, the officer in command is Capt. William L. Mann. The new institute is a component part of the Naval Center at Bethesda which includes also the Naval Medical School, the hospital and the dental school.

NAVY DENTAL OFFICERS ORDERED
TO MAYO FOUNDATION

The following six U. S. naval dental officers have been ordered to the Mayo Foundation, Rochester, Minn., to pursue a postgraduate course in instruction in maxillofacial surgery: Lieut. Comdr. L. P. Mitchell Jr. and Wilbur N. Van Zile, Lieut. Stephen F. Jensen and Lieut. (j. g.) Alexander D. Bunn, John W. Pepper Jr. and Charles R. Shea. All these officers except Lieutenant Jensen are members of the regular navy.

The special course was instituted through the cooperation of the Mayo Foundation and the Navy Bureau of Medicine and Surgery. Three additional groups of officers will pursue the course during the winter.

PUBLIC HEALTH SERVICE

DR WILE COMMISSIONED IN PUBLIC
HEALTH SERVICE

Dr. Udo J. Wile, professor of dermatology and syphilology in the University of Michigan School of Medicine, has been commissioned medical director (R) in the U. S. Public Health Service for active duty with the Division of Venereal Disease Control. Dr. Wile will conduct a study of all new methods described in recent years by various clinicians for the intensive treatment of syphilis. He will also supervise the quarantine hospitals which the Public Health Service and the states are

developing in critical war areas. These hospitals are for the treatment of prostitutes and recalcitrant persons who are infected with syphilis and who are capable of spreading the disease. The hospitals will be staffed by physicians, nurses and record analysts of the Public Health Service, who will be given special training in rapid therapy under the supervision of Dr. Wile. The first training course will begin in November, with headquarters at Ann Arbor. Some twenty physicians, sixty nurses and twenty record analysts are expected to report for training in the first class.

CIVILIAN DEFENSE

MEDICAL CARE FOR WIVES AND
INFANTS OF MEN IN MILI-
TARY SERVICE

The Office for Emergency Management Office of Defense Health and Welfare Services, has issued Family Security Circular No. 27, which contains excerpts from a memorandum to state health agencies from the U. S. Children's Bureau to the effect that state health agencies may provide medical and hospital obstetric and pediatric care for the wives and children of men in military service under instructions issued by the U. S. Children's Bureau which has set aside for this purpose 10 per cent of its Maternal and Child Health fund B appropriation for the fiscal year 1943, amounting to \$198,000.

A maximum amount of \$10,000 can be allotted to any one state at this time from the fund reserved for this purpose.

Funds will be granted to states only for expenditures in accordance with a plan formally submitted by the state agency and approved by the Children's Bureau.

GUIDING PRINCIPLES

Among the principles suggested as a guide to the development of plans by a state agency are the following:

Eligibility—All expectant mothers in the state who report that the father of the expected child is in military service and not a commissioned officer, and any child under 1 year of age whose father is in military service but not a commissioned officer, should be eligible for obstetric medical and hospital services provided under the Maternal and Child Health program without cost to the family, whenever to the knowledge of the state health agency such medical and hospital services are not otherwise readily available to the patient.

Standards of Medical Care—Medical care provided under the plan should be authorized by the state health agency only when the attending physician is licensed to practice in the state and is a graduate of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association. Antepartum care should be of a quality comparable to that recommended in the Children's Bureau publication 'Standards of Prenatal Care'. Obstetricians and pediatricians who are certified by the American specialty boards, or whose

training and experience meet the requirements of such boards, should be appointed consultants by the state health departments and, whenever possible, be made available for consultation with the general practitioners participating in the plan.

Standards of Hospital Care—Hospital care should be authorized only in hospitals that either have been approved by the American College of Surgeons or have been inspected and approved by the state health agency as meeting the standards of an obstetric and pediatric service established by the state health agency. A minimum of ten days' hospital care after delivery should be authorized.

CIVILIAN DEFENSE STAFF MEMBERS AND
FIRST AID TRAINING

James M. Landis, director of the Office of Civilian Defense, announced on November 5 the removal of the requirement that members of staff units of the Citizens Defense Corps have ten hours of first aid training as staff unit members would be employed in the headquarters of the Defense Corps rather than at the scene of air raid emergencies. Air raid wardens, auxiliary police and auxiliary firemen, decontamination squads, messengers and members of the drivers corps each are still required to have at least ten hours of first aid training. The nurses' aides are required to take the regular first aid instruction in addition to the nurses' aide course of eighty hours special American Red Cross training given in connection with approved hospitals. The medical corps, a professional group, has special training as directed by the Office of Civilian Defense Emergency Medical Division. About 175,000 persons have registered for duty with staff units of the Citizens Defense Corps and have taken first aid training similar to that of the wardens and other corps units.

CIVILIAN DEFENSE APPOINTMENT

Dr. Mark V. Ziegler, Chicago, recently resigned as director of district number 3 of the U. S. Public Health Service to become regional medical director of the Office of Civilian Defense in Baltimore.

MISCELLANEOUS

HOW TO CONSERVE MEDICAL AND SURGICAL RUBBER GOODS

Of all the materials which must be conserved to the utmost, rubber is probably most important. By far the biggest "source" of rubber will be the saving of citizens of this country which can be accomplished by taking proper care of the rubber goods they now have. It is possible to extend the life of rubber goods as much as 50 per cent by observing a few simple principles.

SOME GENERAL PRINCIPLES

The greatest enemies to the long life of rubber are sunlight, heat, oils, greases and solvents. To preserve rubber goods the following general rules should be observed:

- 1 Clean and dry rubber goods thoroughly before storage.
- 2 Store in a cool, dark and dry room, away from sources of heat. (New goods should be kept in their boxes.)
- 3 Lay rubber articles flat when storing, allowing them to assume their natural position. Rubber under a permanent strain loses its life and will set up a deformation which may cause it to crack.
- 4 Wash with soap and water or alcohol as soon as possible after contact with oils, greases and solvents.
- 5 Handle rubber goods carefully and avoid puncturing with sharp instruments or the finger nails.

SURGEONS' RUBBER GLOVES

Insist that gloves be put on and removed carefully, and caution all wearers to avoid cutting or puncturing the glove while in use. When drawing on or removing a rubber glove, one should take care that the finger nails of the person holding the gloves do not tear into the rubber. Gloves should be rinsed in cold water after use and before removing them. Gloves should be washed and scrubbed with a brush, using soap and water, before sterilization. Care should be taken to see that all traces of soap or oily substances, they should be soaked for fifteen minutes in a good grade of commercial acetone. Gloves should be tested for leaks by filling them with water under slight tension rather than under air pressure. After gloves are powdered evenly on both sides with talc, they should be allowed to dry away from any form of intense heat. It is particularly important that all air be removed from the sterilizer prior to the sterilization period. A very slight amount of air left in the sterilizer will result in extensive oxidation and deterioration of the rubber. A study made by the Bureau of Standards in 1937 showed a wide variation in the sterilizing methods in use in hospitals. In some instances excessive oxygen was present causing rapid deterioration of rubber products. When sterilization is begun, the air in the sterilizing chamber should be displaced by steam as quickly and as completely as possible. In sterilizing the gloves, the period of exposure should be fifteen minutes at 250 F. The gloves should be removed immediately after the fifteen minute period. Timing the exposure should begin when the thermometer shows 240 F in its advance toward the maximum of 250 F. A longer exposure period reduces the tensile strength and results in reduction in the useful life of the gloves. Several hospitals have reduced the number of gloves used per operation from an average of three or four to less than one simply by reducing the period of exposure in the sterilizer from thirty minutes to fifteen minutes. A rest of twelve hours after sterilization and before use is recommended to prolong the life of the glove and insure better service. Authorities on the proper methods of cleaning rubber gloves agree that chemical germicides and disinfectants, including cresol compounds, should be avoided.

MOLDED RUBBER GOODS

The water used in a water bottle should in no case have a temperature higher than 140 F. Boiling water ages the rubber prematurely. A water bottle should be filled to two thirds capacity with hot water. The bottle should then be squeezed to expel the air in the bottle and the stopper inserted. There should be no air in the bottle when in use. Punctures to water bottles would be greatly reduced if the bottles instead of being

pinned in cloth before being applied to the patient's body were placed in a bag fitted with drawstrings. Ice for throat collars and ice caps should be chopped into fine pieces before and not after it is placed in the bag. The metal shutoff device on the tube of a syringe or enema bag should not be left clamped down. This will weaken the tubing at this point and frequently cause the two inside surfaces to stick together. The shutoff valve should be moved to different points on the tubing to prevent creating a permanent dent at any one point. After use, these items should be thoroughly drained and dried. If an antiseptic or other solution has been used they should first be rinsed out with clean warm water. Before storing they should be inflated so that the sides will not stick together.

SURGICAL TUBING

Clean and rinse rectal tubes thoroughly and then boil for two minutes. Stomach tubes should be rinsed and thoroughly cleaned and then soaked in a 5 per cent solution of cresol for one hour.

RUBBER SHEETING

Rubber sheeting should be washed with soap and warm water, thoroughly rinsed and then cleaned with a 5 per cent solution of cresol. When it is not being used, cover evenly with talc and roll on a tube. Do not fold, as this material has a tendency to deteriorate at the line of folding.

RUBBER FLOORING

Unpolished rubber floors or tile should be cleaned by brushing with a push broom and washing small sections of the floor at a time with a mild solution of washing soda or trisodium phosphate. The solution is made by dissolving about $\frac{1}{4}$ cup of the cleanser in 12 to 16 quarts of clear cold water. All traces of the cleaning solution should be removed by mopping the floor thoroughly with clear water. This process should be continued over the entire floor. A buffer should not be used for scrubbing. Brushing the floor often makes frequent cleaning unnecessary. When the floor has been dried and buffed, it may be waxed by applying a good quality water emulsion wax. Waxes used on rubber floors should be free of oil, fats and organic solvents.

RUBBER TIRES AND WHEELS

Avoid as far as possible running rubber tired equipment over greasy or oily floors. Some reclaimed rubber will be allowed for the replacement of rubber tires on certain types of essential hospital equipment. Any such allotment will however be made only for equipment used near patients' rooms or operating areas.

REPAIRING RUBBER GLOVES WATER BOTTLES AND ICE PACKS

Because of the high quality rubber used in them it is particularly necessary that rubber gloves be repaired where possible and their life extended to a maximum. Cuts, tears and punctures if not too large, can be repaired by applying a patch of thin sheet rubber with a general purpose rubber cement. The cuffs of discarded gloves can be used to make such patches or thin rubber sheeting may be obtained for this purpose. It is desirable to have the patch extend about $\frac{1}{2}$ inch about the damaged area. For very small holes or punctures not more than $\frac{1}{4}$ inch overlap is necessary. The patch will be less likely to be removed if the glove is turned so that the patch is applied on the inside. Gloves which have been properly patched with rubber cement will withstand sterilization satisfactorily. The directions given for patching rubber gloves will also apply to hot water bottles and ice packs.

A NONINJURIOUS SUBSTITUTE FOR GLYCERIN LUBRICATING JELLY

The shortage of glycerin and gums has made it increasingly difficult for doctors in hospitals to obtain adequate supplies of these materials for lubricating gloves, catheters and other surgical rubber products. Realizing this situation, the Canadian Hospital Council requested the Ontario College of Pharmacy to investigate and develop if possible a product which would not require either glycerin or gum and would be satisfactory to the profession. Such a product was developed by Mr. D. E. MacKenzie, assistant professor of pharmacy in the Ontario

College of Pharmacy The method of preparing material was described in the July 1942 issue of the *Canadian Medical Association Journal*. The following is quoted from that article:

It was found that the following formula would meet these requirements:

Starch	7 ounces 135 grams
Distilled water	1 gallon
Sodium lactate (60 per cent)	90 fluidounces
Mercuric oxycyanide	280 grains

Dissolve the mercuric oxycyanide (B P) (sol 18 W) in part of the distilled water, using the remainder of the water to form a smooth paste with the starch. Combine these two portions with the sodium lactate and heat in a steam kettle or some other device capable of supplying a temperature of approximately 100 C. The heating, with moderate agitation is continued until a translucent jelly is formed at which point the product can be at once transferred to suitable containers.

STERILIZATION

The product is best sterilized after it has been placed in containers and following latest approved procedure can be successfully rendered sterile by autoclaving at a steam pressure of 10 pounds (115 C, or 240 F) for a period of thirty minutes.

CONTAINERS

Undoubtedly the collapsible tube is the most satisfactory package. Since tin has gone to war almost 100 per cent and alloy tubes cannot be supplied in very large quantities it might be advisable to standardize, for the time at least, on glass or porcelain jars. These jars could be large enough for only a single application or else packed in larger quantities and resterilized after usage. If jars are used, the tops may be conveniently covered by a triple thickness of cellophane held in place with string or rubber bands and for added protection a further covering of parchment type paper. Autoclaving may be carried out quite effectively while the container is so wrapped.

PUBLIC HEALTH UNDER HITLER

Paris-Son of September 16 reports that winter food conditions will be hard. The meat situation is paradoxical: there are too many animals and too little meat. The number of live stock has been reconstituted with astonishing rapidity since the war, but their market value is disconcerting. Thus, in some markets today a calf sells for less than a goose. Lack of forage due catastrophically to drought has increased slaughtering, but especially of thin animals. Instead of giving 300 to 350 Kg of meat which can be preserved for one year in a refrigerator, an ox gives 250 Kg of second class meat which can be preserved for only a few months. It was originally planned to place 30,000 tons of meat in refrigerators. Last year 24,000 tons was frozen but this year one must be satisfied if 20,000 tons can be refrigerated. The production of pigs of which France consumed 20,000 tons before the war, is at a last gasp owing to a shortage of pig food. Official prices are also unfavorable. A young pig costs 700 francs. Nevertheless it is hoped to maintain level meat rations this winter. Stocks of dried vegetables are almost exhausted. The prospects of the present crops are poor. This is the biggest question of the coming winter.

Ny Dag of September 16, dealing with the experiences of the shipwrecked crew of the mined Swedish vessel *Tynningöe* on its return from Germany, states that their recollections of their stay in Germany are unpleasant. Not a piece of soap is obtainable, and the food is extremely bad. They saw, however, that Germans fared no better and that there is appalling want. Their general impression was that the Germans are longing intensely for peace regardless of who wins. The British bombing raids over western Germany have a frightful effect. The seamen traveled through Rostock and Emden where all important buildings seemed destroyed.

According to the *Frankfurter Zeitung* of September 11 in order to recover the celluloid from many millions of old toothbrushes firms in the toothbrush industry will in future require that the purchase of new toothbrushes be made conditional on the return of the old ones.

In the *Helsingin Sanomat* of September 14 a correspondent writes: "The question of the saccharin shortage was discussed in the press last summer, when we were assured that the supply would shortly improve, but so far there is no sign of saccharin on the market. We were told in shops that it had all gone to the foreigners." We were also told that it has become quite impossible to obtain this commodity from abroad. What is the real truth about saccharin?"

According to *Magyar Szociális Szemle*, August, Dr. Sandor Mozolovszky dealing with industrial accidents, reports that during 1941 there were 3,224 fatal accidents and over 30,000 minor ones. The number of working hours thus lost has not been published. Judging from personal experience, these may be estimated without exaggeration at 677,040. If the loss of one day's work is estimated at 5 pengos the total loss suffered would amount to 3,385,200 pengos.

According to DNB of August 26, the fuhrer has issued the following decree on the medical and health services:

The employment of the personnel and the material in the medical and health services must be controlled in a uniform manner and according to a preconceived plan. I therefore order as follows:

1 In the sphere of the armed forces I commission the inspector of the medical service of the army in his capacity of chief of the medical service of the armed forces, to correlate all joint tasks in the sphere of the medical services of the armed forces, the Waffen-SS and the organization and units under the command of or attached to the armed forces, at the same time retaining the duties which he has discharged hitherto.

The chief of the medical service of the armed forces represents the armed forces in all matters common to the medical services of the different services, the Waffen-SS and the organizations and units under the command of or attached to the armed forces, with all other authorities and looks after the interests of the armed forces with regard to the hygienic measure taken by the civil administration.

For dealing comprehensively with these tasks one medical officer each from the navy and the luftwaffe shall be attached to him in the capacity of chief of staff. Questions of principle concerning the medical service of the Waffen-SS must be settled in agreement with the medical inspectorate of the Waffen-SS.

2 In the sphere of the civilian health service the secretary of state in the reich ministry of the interior and reich health leader Dr. Conti is responsible for all uniform measures. For this purpose the departments concerned of the supreme reich authorities and their subordinate authorities are at his disposal.

3 For special tasks and negotiations in order to balance the requirements of (doctors, hospitals), medicines and so on between the military and the civilian sectors of the medical and health organization I confer full powers on Prof. Dr. Med. Karl Brandt who is responsible to me personally and takes his orders from me.

4 My Delegate for the Medical and Health Organization must be kept informed of any events of fundamental importance both in the medical service of the armed forces and in the civilian health service. He is authorized to take action on his own responsibility.

"Signed by the fuhrer by Keitel as chief of the OKW and by Lammers as head of the reich chancellery."

Prof. Dr. Med. Brandt will have the title of 'Commissioner General of the Fuhrer for the Medical and Health Services'."

Hrvatski Narod of August 29 reviews the work of the past year in Bosnia of the Institute for Diseases, which estimates that within two or three years it will be able entirely to suppress endemic syphilis in the country. During the past year more than sixty doctors have been working and over one hundred clinics operating. 365,980 persons have been treated, 295,345 injections given and 32 Kg of arsenicamine and 244 Kg of bismuth compounds used.

Zora of August 2 reports that a special train with 300 wounded German officers and men from the African front have arrived at Skopje. They were in very high spirits.

According to the *Berliner Börsen Zeitung* of August 9 the Bad Pyrmont, one of the largest and best known watering places of greater Germany, is today almost entirely at the service of the Wehrmacht. It was certainly not an altogether pleasant surprise when immediately after the outbreak of war the greater part of all hotels, boarding houses and houses designed to receive private guests were commandeered by the Wehrmacht. It meant adapting oneself to the new arrangement, which was not easy at first. The willingness and cooperation of the population and the authorities of Bad Pyrmont alike enabled the creation of an organization by means of which thousands of German soldiers are able to regain their health. Radical interference everywhere, especially in the plans of private guests from all over the Reich, was necessary.

The task of organizing was huge. The fact that a medical officer with the high rank of oberstabsarzt has been entrusted with the running of Pyrmont (Reserve-lazarett Bad Pyrmont is its correct name) is proof of the importance of the undertaking. Both from a medical and from a disciplinary point of view, all the members of the armed forces in the place are under him.

Pyrmont offers ideal conditions for the wounded and the sick. The healing power of the springs, the mud baths, the mineral water and sun bathing treatments promise recovery from the prolonged ailments which especially the hard winter at the eastern front brought to so many German soldiers: rheumatism, neuralgia, heart diseases and so on. There are over 2,500 beds at the disposal of the Wehrmacht.

BLANKETS FOR RUSSIAN HOSPITALS

Russian War Relief Inc., 11 East Thirty Fifth Street, New York, announced on October 29 the purchase for Russian hospitals of sixty thousand blankets which had been urgently requested by Soviet medical authorities. A part of the total number purchased has already been shipped. The Maple Leaf Fund contributed four thousand eight hundred blankets to Russian war relief.

AMERICAN MEDICAL MEN HONORED FOR SERVICES TO CHINA

Dr Wei Tao-ming, Chinese ambassador to the United States, awarded "Medals of Honored Merit" to seven Americans for wartime services to China at a meeting on October 27 of the American Bureau for Medical Aid to China, participating agency of United China Relief. Six of the recipients were physicians or scientists. Those honored were Dr R. R. Williams of the Bell Telephone Laboratories, a collaborator in the isolation of vitamin B₁, who has, through the American Bureau for Medical Aid to China, advised Chinese health agencies on vitamins in wartime diets, Aura Severinghaus, chairman of the bureau's library committee, who devoted a sabbatical year to collecting textbooks for China's medical schools, has developed microfilm copies of these libraries and has prepared a set of microscopic slides for teaching anatomy in China's medical schools, Dr John Scudder of the surgical staff of Presbyterian Hospital, New York, who conducted a nationwide appeal to his colleagues for surgical instruments for use in China, Dr G. Canby Robinson of Baltimore, honored for long service as chairman of the Baltimore chapter of the bureau, Dr Walter Judd for devoted service as a physician in China for many years and for his part in arousing America in aid of China, Miss Rebecca Griest for her work in organizing medical aid for China and in the development of the bureau, and Dr Claude E. Forkner, assistant dean of clinical medicine at Cornell University for services as a member of the medical committee of the bureau and for helping to solve problems of child welfare in China.

Dr Frank L. Meleney, chairman of the medical committee of the bureau, reported that, since May, four doctors and a sanitary engineer had been sent to China by the bureau and that three other technicians were preparing to return to China. These doctors and technicians, all Chinese, are to serve in China either with the National Health Administration or with the emergency medical service training schools of the Chinese army. The medical committee also has furnished information to government agencies here on the drug situation in China and has worked out a plan for drug manufacture in China. Subcom-

mittees on nursing, public health and medical education are working in close cooperation with health agencies in China to furnish these agencies with technical assistance.

Dr Co Tui, chairman of the China program committee of the bureau, reported that the bureau was supporting in China maternity and child health programs, medical education, the army medical service and the epidemic control work and public health program of the national health administration.

"HUTTED" HOSPITALS

Fifty one thousand beds have been added to England's hospital accommodations by means of single story hutments, according to the English minister of health as quoted in a recent issue of the *Hospital*. Some of these are complete self contained hospitals and others are extensions to existing hospitals. The minister of health is quoted as saying that "In building and planning them we have learnt many useful lessons that should stand us in good stead in evolving the ideal hospital of the future. We may have learnt too that it is not necessarily true economy to design a hospital to last one hundred years in an age in which medical knowledge and requirements are developing as never before." He suggested that the temporary hutted hospital affords an ideal transitional stage between the traditional hospital and the hospital that will emerge after the war.

THE FEEDING OF DOGS

The Office of War Information has released the following information concerning the feeding of dogs during the government's newly inaugurated voluntary "Share the Meat" program.

Long established practice has set up a belief among dog owners that the mainstay of the canine diet must be red muscle meat, preferably beef, but according to Dr Imogene P. Earle, nutritionist in the Bureau of Animal Industry, U. S. Department of Agriculture, red muscle meat can be taken away and the dog kept perfectly healthy and strong. One should be sure, however, that the protein iron and vitamin content of the meat is replaced in the dog's diet. This can be done in several ways. In the voluntary "Share the Meat" plan for dog owners the glandular meats are not included in the week's limit of 2½ pounds per person. Not only can the owner eat as much of these as he wishes but he can give them to his dog too. Hearts, kidneys, liver, spleen and brains, lightly cooked, are even better for the dog, Dr Earle says, than the muscle meats usually fed to him. Poultry, which is not included in the voluntary meat ration, is a good source of protein. Fish, well cooked and eggs are, in Dr Earle's opinion, very good for dogs. Dr Earle says that milk is an especially good source of protein and calcium and that dried skim milk may under some conditions be the most economical and convenient way to feed milk to an animal.

From 20 to 22 per cent of the dog's diet should be protein, preferably from animal products such as those already mentioned. But animal proteins can be combined with vegetable proteins. Pea soup, for example, made with protein high dried peas and milk is an excellent dish for the dog. So is peanut meal or soy bean meal mixed with milk, and cooked cereals or bread and fed as a mash. Dehydrated dog foods can be enriched with milk or with gravy from the family roast, or with the water in which vegetables are cooked. If the dog's owner wishes to mix an adequate feed at home, the following ration based on a requirement of 1 pound of dry feed a day is suggested. The starred items are obtainable at feed stores.

*Yellow corn meal	scant ½ pound
*Wheat shorts	scant ¼ pound
*Peanut meal	generous ¼ pound
*Bone meal	¼ ounce
Salt	a pinch
Leafy greens or carrots	2 or 3 tablespoons

The ingredients may be cooked either before or after mixing but too much cooking destroys some of the vitamin content. To moisten meat gravy soup or the water in which vegetables have been cooked should be used. Contrary to popular opinion Dr Earle says there is no harm in feeding potato or other starchy foods, provided the cell structure is properly broken down by cooking and by grinding or mashing. Fruits, especially prunes, peaches and apricots, are good for dogs, and there is no harm in fats if the dogs exercise a good deal.

ORGANIZATION SECTION

OFFICIAL NOTES

PREMEDICAL EDUCATION

For the duration of the war the Council on Medical Education and Hospitals of the American Medical Association recommends that

1 The required premedical education, including satisfactory courses in physics, biology and chemistry, including organic chemistry, shall be included within two calendar years of instruction.

2 The first year of premedical education shall be considered as a qualifying year for a medical course. At the termination of this first year the student, if acceptable, should be matriculated in a medical school.

3 Such a matriculated student shall be recommended for enlistment or commission in the Army or Navy to remain in an inactive status during the second year of his premedical course and until the completion of his medical training, subject to the maintenance of adequate grades.

4 The medical schools accepting students under these conditions will in no way jeopardize their status with any accrediting agency.

The Council and the Association of American Medical Colleges in February 1942 recommended the adoption of an accelerated program involving the completion of the medical course in three calendar years. Such a program is already in effect in practically all the medical colleges of the country.

These further recommendations adopted by the Council at its Nov. 8, 1942 meeting involve a program providing for the completion of a student's medical education and the granting of the M.D. degree within a period of five years after graduation from high school as contrasted with seven to eight years before the

war. Thus medical education has cooperated in the war effort to increase the supply of physicians by speeding up its program so as to shorten the period required for the M.D. degree by from two to three years.

The Association of American Medical Colleges adopted similar recommendations at its annual meeting held in Louisville on Oct. 27, 1942.

Such a program as has been recommended would involve the protection of between nine and ten thousand students during the first year of their premedical college training in order to provide approximately six thousand five hundred satisfactory matriculants for the medical schools of the country on the completion of this first year of college.

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE

The Council on Medical Education and Hospitals of the American Medical Association, at a meeting held on November 5, restored the University of Georgia School of Medicine to the list of approved medical schools maintained by the Council with the status of being on probation.

This action restores to the University of Georgia School of Medicine and of all its matriculated students all advantages which may accrue to colleges included in the list of approved medical colleges maintained by the Council.

Probationary status indicates that there are certain factors or relationships which should be clarified before the Council grants unqualified listing of a school as an approved medical school.

WOMAN'S AUXILIARY

Mississippi

The auxiliary to the Northeast Mississippi Thirteen Counties Medical Society held its quarterly meeting September 8, in Amory at the home of Mrs. M. Q. Ewing. The president, Mrs. Stanley A. Hill of Corinth, presided. The program included two honored guests—Dr. Shelton Horsley of Richmond, Va., and Dr. Seale Harris of Birmingham, Ala.—both of whom placed importance on the work doctors' wives can do in enlightening the public. Dr. Horsley emphasized the control of cancer. Dr. Harris discussed foods, with special attention to the vitamins. He also made a comparison of the physical fitness of our armed forces in World War I and in the present war.

Oregon

The annual meeting of the executive board of the Woman's Auxiliary to the Oregon State Medical Society was held September 12 in Portland. Mrs. C. E. Hunt, the president, presided.

Mrs. F. Bertram Zener of Portland was elected president for the coming year and Mrs. Grover C. Bellinger of Salem, president-elect. At the luncheon a saddle bag 150 years old was presented to the auxiliary by Dr. George Hayden Westerfield and a small surgical kit by Dr. Alfred C. Kinney. Dr. Westerfield, now 84 years old, said that the saddle bag had been carried by his father in the war of 1812. Dr. Kinney, who was the first as well as the fiftieth president of the Oregon State Medical Society, is now 92 years old. His gift was dated 1871 and had belonged to his brother Dr. Augustus C. Kinney.

It was decided that for its major project this year the auxiliary would concentrate on working with the Medical and Surgical Relief Committee of America in collecting all kinds of surgical equipment including old instruments which can be reconditioned and made available for civilian defense needs or for distribution to foreign relief through the proper agencies.

Pennsylvania

The Schuylkill auxiliary met June 9 at the home of Mrs. J. Edward McDowell in Pottsville. After the business session a talk on "Flower Arrangements for the Home" was given by Mrs. Henry Houch, Weston Place. A plant sale was conducted and a soldier doll wearing new \$1 bills was awarded, about \$30 was realized from this project alone. The proceeds will go to the Medical Benevolence Fund. More than 60 persons attended.

Wisconsin

Twenty-one members and two guests were present at the meeting of the Woman's Auxiliary to the Washington Ozaukee County Medical Society, held recently at the home of Mrs. K. L. Bauer in West Bend. Mrs. R. E. Fitzgerald of Wauwatosa, who has been president of the state and of the national auxiliary, discussed five books: "Ivory Mischief" by Arthur Meeker Jr. of Chicago, "Windswept" by Mary Ellen Chase, "Mrs. Appleyard's Year" by Louise Andrews Kent, "Dragon Seed" by Pearl Buck and Robert Nathan's "A Winter Tide."

Fifty members attended the May meeting of the Woman's Auxiliary to the Milwaukee County Medical Society. Mrs. Angelo Hofman, Clarence Slater, Read Widrig and G. Maasen gave a piano duo. Miss Doris Brockway, instructor in home economics at Milwaukee Downer College, spoke on "New Fabrics the War Has Given Us."

At a meeting of the auxiliary to the Sheboygan County Medical Society at the home of Mrs. Alton J. Schmitt, Mrs. L. F. Pauly spoke on "Good Health in Ecuador," and Mrs. Paul B. Mason reported on "Nutrition."

Every member who had not contributed before gave \$1 to the cancer fund being raised by the Women's Field Army for the Control of Cancer. The auxiliary voted to give \$15 for the purchase of utility kits for the Red Cross.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Alien Japanese Physician Sentenced for Abortion—Dr. Hirosaki Ben Inouye, Phoenix, formerly of Glendale, was sentenced to a term of three to five years following conviction on a charge of performing a criminal abortion on a 21 year old woman. According to the *Arizona Republic*, October 14, the jury acquitted him of second degree murder in connection with the death of the woman. Dr. Inouye was born in Japan in 1901, graduated at the Chicago Medical School in 1935 and was licensed to practice medicine in Arizona, Jan. 6, 1937.

CALIFORNIA

Quinine Found in Home for Aged—A recent survey of institutions under the control of Dr. Jacob C. Geiger, director of public health of the city and county of San Francisco, revealed 82,700 gelatin coated pills of quinine sulfate in the Lagnuna Honda Home, an institution for aged indigent ill. The pills had been in the institution since 1906. An arrangement was made by the controller of the city whereby the capsules were turned over to the U. S. Army.

CONNECTICUT

Fined for Practicing Without License—Dr. Ray D. Hester, Granville, Mass., was fined \$200 after pleading nolo contendere to a charge of practicing medicine in Hartford without a state certificate of registration, the *Hartford Times* reported October 14. Dr. Hester is licensed to practice medicine in Massachusetts but is not licensed to practice in Connecticut. The *Times* pointed out that Dr. Hester had distributed cards which said that he would pay toll charges on calls to Granville from Hartford and Granby, just over the state line from his home, where he has practiced since 1939. Dr. Hester graduated at the College of Physicians and Surgeons, Boston, in 1939.

Neuropsychiatric Institute Affiliates with Columbia University—A professional affiliation between the department of nursing of Columbia University College of Physicians and Surgeons (Presbyterian Hospital School of Nursing in the city of New York) and the Neuro-Psychiatric Institute of the Hartford Retreat has been announced. Under the affiliation, students with university degrees who are receiving advanced time credit in the department of nursing at Columbia will undertake an intensive two months course in neuropsychiatric nursing at the institute under the direction of the institute's medical and nursing staffs. Fifteen students are expected to begin classes in December.

ILLINOIS

Personal—Dr. Louis Belinson, Dixon, assistant managing officer of Dixon State Hospital has been appointed acting managing officer of the Lincoln State School and Colony, Lincoln, succeeding Dr. Richard J. Graff, Lincoln.

Chicago

Joint Session on Heart Disease—The Chicago Medical Society and the Chicago Heart Association will hold a joint meeting at the Chicago Woman's Club, November 18 to hear the following speakers: Drs. Stanley Gibson on "Treatment of Heart Disease in Children," William A. Brams, "Treatment of Heart Failure" and Newell C. Gilbert, "Treatment of Coronary Thrombosis."

Course in Electrocardiographic Interpretation—A course in electrocardiographic interpretation for graduate physicians will be given at the Michael Reese Hospital by Dr. Louis N. Katz, director of cardiovascular research. The class will meet each week, starting Wednesday, February 17, for twelve weeks, from 7 to 9 p. m. Information may be obtained from the cardiovascular department, Michael Reese Hospital, Twenty-Ninth Street and Ellis Avenue.

Lectures on Emergency Medical Service—On October 26 James K. Senior, Ph.D., research associate in chemistry, University of Chicago, gave the first in a group of three lectures on emergency medical services sponsored by the Office of Civilian Defense Chicago Metropolitan Area. Dr. Senior

discussed general aspects of gas warfare with particular reference to the defense of the Chicago area. Dr. Franklin C. McLean, professor of pathologic physiology at the University of Chicago, spoke, November 2, on lung injuries and systemic poisons: pathology, first aid and therapy. Dr. William Bloom, professor of anatomy, University of Chicago, lectured, November 9, on vesicants, lacrimators and sternutators: pathology, first aid and therapy.

INDIANA

District Meeting—The sixty-eighth semiannual meeting of the Indiana Eleventh Councilor District Medical Association was addressed in Peru, October 21, by Dr. Fredrick F. Younkman, Detroit, on "The Sulfa Drugs", Commander Robert H. Collins, M.C., U. S. Navy, Washington, D. C., "Some Experiences in Twenty-Seven Years in the Navy," and Dr. Ross C. Ottinger, Indianapolis, "Conservative Pelvic Surgery."

Dr. Rice Named Acting State Health Commissioner—Dr. Thurman B. Rice, health education consultant, state board of health, Indianapolis, has been appointed acting state health commissioner. Dr. John W. Ferree, Indianapolis, has been granted leave of absence as state health commissioner to serve as lieutenant commander in the medical corps of the U. S. Navy. Dr. Ferree has been state health commissioner since October 1940. He had also served as chief of the bureau of local health administration. Dr. Rice, until his recent appointment as health education consultant was chief of the bureau of health and physical education. He is also editor of the *Monthly Bulletin* of the state board of health.

LOUISIANA

Personal—Dr. Eugene H. Countiss, New Orleans has been named chief of the emergency medical service in Louisiana. —Marion Winfred Hood, Ph.D., formerly associate in medicine at the University of Illinois College of Medicine, Chicago, has been appointed assistant professor of parasitology in the department of public health at Louisiana State University School of Medicine, New Orleans. —Dr. Edgar W. Warren, Abbeville, director of the Vermilion Parish Health Unit, has been appointed to a similar position in Jefferson Parish. —Dr. Bjarne Pearson, New Orleans, has been appointed associate professor of pathology and bacteriology at Tulane University of Louisiana School of Medicine, New Orleans. —Dr. Jacob Katzeff, formerly of Brooklyn, N. Y., has been appointed health officer of La Fourche and Assumption parishes.

MARYLAND

Dr. Robert Patterson Named Dean at Maryland—Major Gen. Robert U. Patterson, U. S. Army, retired, formerly surgeon general, has been appointed dean of the University of Maryland School of Medicine and College of Physicians and Surgeons and superintendent of the University Hospital in Baltimore. Dr. Patterson was dean at the University of Oklahoma School of Medicine, Oklahoma City, where he recently reached the retirement age. He graduated at McGill University Faculty of Medicine, Montreal in 1898 and was an honor graduate of the Army Medical School, Washington, D. C., in 1902. Dr. Patterson succeeds Dr. Hamilton Boyd Wylie, Baltimore, who has been acting dean of the University of Maryland School of Medicine since the retirement of Dr. James M. H. Rowland, Baltimore, in 1939.

MICHIGAN

Training Program for Physicians in Industry—The bureau of industrial hygiene of the Michigan Department of Health will conduct a short training course in Lansing for physicians expecting to serve in industry. The first week of the three week course will be confined to didactic work covering the preventive aspects of industrial medicine. The second week will be devoted to field work including visits to industrial plants investigating actual hazards and determining the extent of exposure. During the third week physicians will be assigned to full time medical departments in various industries to observe the actual work of those departments. No charge will be made for any of the work covered during the period but it is expected that those enrolling will defray their own living expenses. The plans for the course were developed through the cooperation of the Procurement and Assignment Service, Subcommittee on Industrial Health and Medicine, Social Security Agency, Council on Industrial Health of the American Medical Association, Committee on Industrial Health of the Michigan State Medical Society, and the Bureau of Industrial Hygiene of the state department of health.

NEVADA

State Medical Election—Dr John R McDaniel Jr Las Vegas, and now in military service will be continued as president-elect of the Nevada State Medical Association until such time as he can assume the office, in accordance with action taken during the recent annual meeting of the association. Dr Daniel J Hurley, Eureka, first vice president, was inducted into the presidency and Dr Lemuel R Brigman, Reno second vice president, was moved forward to fill the first vice presidency. Dr John A Fuller, Reno, was chosen second vice president and Dr Roland W Stahr, Reno, was chosen secretary-treasurer to take office January 1. During the annual dinner Dr Horace J Brown Reno, who has been secretary for many years was presented with a watch and chain to mark his completion of twenty-five years' service as an officer and adviser.

NEW HAMPSHIRE

Personal—Dr Edward S Thorpe, formerly of Philadelphia has been appointed medical director of the St Pauls School and will be associated with Dr Carleton R Metcalf, Concord, school physician.

Staff Changes on State Board—Dr Mary M Atchison for some years director of the divisions of maternal and child health and crippled children's services and acting director of the division of epidemiology and local health work, was recently named acting deputy secretary of the state board of health. In her new position Dr Atchison will cooperate with local health authorities in the promotion of community health programs. Dr Mildred I A Chamberlin Hillsboro succeeded Dr Atchison as director of the division of maternal and child health and crippled children's services. The divisions of epidemiology and venereal disease control have been consolidated. Dr Cleon W Colby, health officer of Exeter District has been named acting director. For the present Dr Colby will continue in charge of the Exeter office.

NEW JERSEY

Oil Products Company Expands—The National Oil Products Company, Harrison, recently announced that it had acquired Rare Chemicals, Inc., at Flemington, and was planning a program of expanded production of specialized drugs and pharmaceuticals. The 7½ acre Flemington plant was acquired by the company in the first sale by the alien custodian's office of any of the properties that have been seized from foreign nationals. It will be operated as a wholly owned subsidiary and will have its own board of directors and officers. The announcement stated that production of the chemicals and other products formerly manufactured by Rare Chemicals would be expanded as rapidly as circumstances would permit. Among the products now being manufactured at the plant are anesthetics, hormone substances and analgesics for ethical distribution.

NEW YORK

Psychiatric Survey of Men Classified Under Selective Service—The New York State mental hygiene committee of the State Charities Aid Association has been directing a psychiatric classification of men examined for Selective Service to secure social histories for use by examiners. Up to October 1, more than 17,000 Selective Service registrants had been investigated. The New York City Committee on Mental Hygiene has been carrying on a similar project, both programs being intended to aid in deferring men who are poor risks for the army because of abnormal mental conditions. Under the state plan, the advisory committees were appointed in each county, which in turn recommended social workers for each board in the county and also assisted in training the social workers selected.

New York City

Second Harvey Lecture—Curt P Richter Ph D associate professor of psychobiology Johns Hopkins University School of Medicine Baltimore, will deliver the second Harvey Society Lecture of the current series at the New York Academy of Medicine November 19. He will speak on Total Homeostasis.

Dr Thomas Dublin Appointed Professor—Dr Thomas D Dublin epidemiologist in the state division of communicable diseases Albany has been appointed head of the department of preventive medicine and community health at the Long Island College of Medicine effective September 21. Dr Dublin graduated at Harvard Medical School, Boston in 1936. He has a degree of doctor of public health from John Hopkins University School of Hygiene and Public Health Baltimore.

Session on Chronic Pulmonary Diseases—The Tuberculosis Sanatorium Conference of Metropolitan New York will conduct a clinical session on chronic pulmonary diseases at the Cornell University Medical College Amphitheater, December 9. The speakers will be Dr Herbert R. Edwards, Lieut Col Edward N Packard, M C, U S Army, Fort Dix, N J, and Lieut Comdr David Ulmar, M C U S Navy, Chelsea, Mass, and Major Freeman Nathan, Fort Jay. Dr Edgar Mayr assistant professor of clinical medicine at Cornell, will lead the discussion at an informal presentation of x-ray films.

Lecture Named to Honor Dr Niles—The annual lecture sponsored by the chapter of Nu Sigma Nu at Cornell University Medical College will henceforth be known as the Walter I Niles Memorial Lecture in honor of the late Dr Niles, who at the time of his death, Dec 22, 1941, was acting dean of Cornell. This year the lecture was given by Dr Irvine H Page, director, Lilly Laboratory for Clinical Research, Indianapolis City Hospital, on October 20. His subject was "The Modern Concept of Hypertension." Dr Niles had been professor of clinical medicine from 1916 until his death and had been dean from 1919 to 1928.

Public Lectures—The second series of lectures to the laity on medicine and the public health will open with a talk, November 19, by Clarence C Little, Sc D, Bar Harbor, Maine, on "The Problem of Cancer." Others in the series will be Drs John A Kohner, Philadelphia, on "Winning the Battle Against Infectious Disease," Thomas D Dublin "Epidemics and World Conflicts," William D Stroud, Philadelphia, "The Fight Against Heart Disease," and Louis Tust, Philadelphia, "Modern Concept of Allergy." The series is sponsored by the Brooklyn Institute of Arts and Sciences, the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn.

Cardiac Programs—The New York Heart Association will hold three scientific sessions at the New York Academy of Medicine instead of four during the coming year. Drs Oswald F Hedley, U S Public Health Service Bethesda, Md, and Rufus B Crum Rochester, N Y, on December 1 will discuss "The Cardiac in Industry." On January 19 a dinner session will be held with the section on medicine of the Academy of Medicine and the topic for discussion will be "Cardiovascular Diseases and Injuries in War." It is anticipated that Dr Philip D Wilson will be the speaker. On March 23 reports of original investigations being conducted in the affiliated cardiac clinics will be presented.

Advisory Committee on Zoology at Columbia—An advisory committee of zoologists from other institutions to the department of zoology at Columbia University has been appointed to serve as liaison between the department and zoologists in other universities. Columbia's department is observing its fiftieth anniversary this year. Members of the new committee include Hubert B Goodrich Ph D, Wesleyan University Middletown, Conn, Edmund N Harvey, Ph D, Princeton University, Princeton N J, Charles W Metz, Ph D University of Pennsylvania, Philadelphia, Hermann J Muller, Ph D, Amherst College, Amherst, Mass, William Procter, D Sc, Academy of Natural Sciences, Philadelphia, Alfred S Romer Ph D Harvard University, Cambridge, Mass and Lorande L Woodruff, Ph D, Yale University, New Haven, Conn.

Committee to Coordinate Wartime Care of Children—On October 22 Mayor La Guardia appointed a committee of fourteen to coordinate all effort in providing daytime care for children of mothers working in defense industries. The appointment of the committee was one of the recommendations of a special committee named last June to study the problem. William Hodson, LL B, welfare commissioner, is the chairman of the new committee and Alice V Keliher, secretary. Dr Ernest L Stebbins commissioner of health, is one of the committee members and also served on the original committee of three named to study the problem. The report makes recommendations which suggest (1) the establishment of eight school nursing centers, supplementing the thirty two now operating under the WPA (2) the extension of its present after-school program for children and (3) the establishment of a central coordinating committee on daytime care of children which recommendation was carried out with the appointment of the new committee. The fourth recommendation urges the establishment of an office of information, advice and consultation where mothers can talk over their problems. The committee of three appointed originally to study the problem and submit a report comprised Welfare Commissioner Hodson, Dr Stebbins and John E Wade, deputy superintendent of the board of education who is also a member of the new daytime committee.

OHIO

Changes in Health Personnel—Dr James F Wilson, Washington Courthouse, has resigned as health commissioner of Wythe County, a position he has held for sixteen years. It is reported—Dr Rush R. Riehlson has been appointed health commissioner of Springfield. He was succeeded as health commissioner of Clark County by Dr Robert M Taylor, North Hampton.

Outbreak of Diarrhea in Newborn Infants—Newspapers reported, October 23, that 16 babies had died in an outbreak of diarrhea among newborn babies in St. Luke's Hospital, Cleveland. The outbreak was first reported in mid-September. The newspapers stated that similar outbreaks were reported to have occurred in Carlisle, Pa., Detroit, Toledo, Dayton and Indianapolis.

Annual Postgraduate Day—The University of Toledo held its annual postgraduate day, November 6, dedicating this year's course to the late Dr Elmer W. Heltman, Toledo, who died March 3, 1906. Speakers included Dr. Brien T. King, Seattle, on "Deep Infections of the Neck" and "A New and Function-Restoring Operation for Bilateral Abductor Cord Paralysis," and Dr. John J. Moorhead, New York.

Course in Gas Warfare—The first of a series of six-hour courses in the medical aspects of gas warfare will be given in Columbus, November 16, 23, 27, under the auspices of the Ohio State University College of Medicine and the Columbus Academy of Medicine. Instructors for the course will be:

- Dr Charles A. Doan, professor of medicine
- Dr Paul H. Charlton, assistant clinical professor of surgery
- Dr Roll H. Markwith, state health director and state director of Emergency Medical Services
- Major W. W. Towne, sanitary engineer of the state department of health
- Mr Merle Paul, state gas consultant
- Mr Howard M. Simmonds, senior & is officer for Columbus
- Dr Clayton S. Smith, professor of physiological chemistry, pharmacology and materia medica
- Dr Albert D. Frost, professor of ophthalmology
- Dr E. Harlan Wilson, assistant professor of surgery (orthopedics)
- Dr Harry L. Reinhart, associate professor of pathology
- Dr Herman A. Hoster, instructor in medicine

All are from Columbus. Similar projects are being planned at the University of Cincinnati College of Medicine and Western Reserve University School of Medicine, Cleveland, for physicians in their respective sections of the state.

OREGON

Personal—Dr Willard J. Stone, Corvallis, has been appointed health officer of Marion County, succeeding Dr. Vernon A. Douglas, Salem, who was on leave of absence for the Oregon Civilian Defense Council.

Annual Registration Due December 1—All practitioners of medicine and surgery holding licenses to practice in Oregon are required by law to register annually on or before December 1 with the secretary of the board of medical examiners and at that time to pay a fee of \$5. A practitioner failing to register is subject to a penalty of \$1 for each thirty days or part thereof of default, and his failure to reregister within ninety days after December 1 is a misdemeanor.

PENNSYLVANIA

Society News—Dr William G. Lennox, Boston, discussed "The Treatment of Epilepsy and Migraine" before the Harrisburg Academy of Medicine, Harrisburg, October 20.—The Reading Eye, Ear, Nose and Throat Society was addressed recently by Dr Alfred Cowan, Philadelphia, on "Interesting Aspects of Refraction."

Science Building Named in Honor of Dr Pfahler—The three-quarter million dollar science building at Ursinus College, Collegeville, was named the Pfahler Hall of Science during the Founders' Day convocation, October 13, in honor of Dr George E. Pfahler, professor of radiology at the University of Pennsylvania School of Medicine, Philadelphia, and a member of the board of directors of Ursinus College since 1935. The principal address during the exercises was given by Dr William David Coolidge, vice president and director of research for General Electric Company, Schenectady, N. Y., on "The Role of Science Institutions in Our Civilization." Dr Pfahler, who was born in Numidia in 1874, graduated at the Medico-Chirurgical College of Philadelphia in 1898 and served there as clinical professor of roentgenology from 1909 to 1912. He has been professor of radiology at the University of Pennsylvania since 1916. Dr Pfahler has been president

of the American Roentgen Ray Society, the American Electrotherapeutic Association, the American Radium Society and the American College of Radiology. He served as an American delegate to the 1928 International Conference on Cancer in London and at the second International Congress of Radiology in Stockholm. He was an honorary vice president of the fifth International Conference on Radiology in 1937 and for the International Conference on Cancer in 1939. The hall of science which was erected in 1931-1932, contains thirteen teaching laboratories, two research laboratories and nine professors' laboratories, seven classrooms and a lecture hall.

Philadelphia

Grant for Study on Renal Hormones—The John and Mary R. Markle Foundation for research has given Temple University School of Medicine a grant of \$2,500 to further the study on "renal hormonal mechanism in hemorrhage, shock and other hormone conditions," now being carried out by Drs. Dean A. Collins, assistant professor of physiology, and Angie G. S. Hamilton. The grant is the second within a few months to be received from the Markle Foundation. The first of \$2,900, received a few months ago, was for a study of body fluids in children with persistent acidosis now being directed by Dr. Waldo E. Nelson, professor of pediatrics.

Report on Physicians' Aid—The Aid Association of the Philadelphia County Medical Society has recently made public its annual report for 1941. The committee on benevolence distributed \$5,424 during the year to annuitants and beneficiaries. Annuitants are elderly and ill physicians unable to support themselves and their families, and widows and daughters of deceased physicians with no income or with income insufficient to supply the necessities of life. Beneficiaries are physicians and widows and daughters of deceased physicians in financial difficulty that appear to be of a temporary character or who needed for a limited period shelter, food, clothing, coal, medicine, dentures, eyeglasses, hospitalization and other essentials. Cash contributions totaling \$4,419 were received consisting of legacies and donations. The membership of the association was increased by sixty-two, fifty-nine new annual members and three new life members. The total active membership as of Dec. 31, 1941 was 498, as compared with 486 for the same date in 1940.

TEXAS

Lecture on X-Rays—Dr. Byrl R. Kirklin, Rochester, Minn., spoke at the fifth in a series of medical conferences sponsored by the Medical Replacement Training Center at Camp Barkeley, Texas, October 30, on "The Value of the Roentgen Rays to Diagnosis as It Pertains to the Physician Doing General Work."

Post Graduate Medical Assembly—The Post Graduate Medical Assembly of South Texas will hold its eleventh annual meeting at the Rice Hotel, Houston, December 1-3. There will be nine guest speakers for the general sessions and four for the section of ophthalmology and otolaryngology which meets independently. On the last day a special program on military and civilian defense will be featured. The guest speakers will include:

- Dr. John C. Burch, Nashville, Tenn., obstetrics and gynecology
- Dr. Robert Gordon Douglas, New York, obstetrics and gynecology
- Dr. Lawrence S. Fallis, Detroit, surgery
- Dr. Roy Biggs, Henline, New York, urology
- Dr. Chester M. Jones, Boston, medicine
- Dr. Carl H. McCaskey, Indianapolis, otolaryngology
- Dr. Donovan J. McCune, New York, pediatrics
- Dr. James H. Means, Boston, medicine
- Dr. Arthur W. Proetz, St. Louis, otolaryngology
- Dr. G. Allen Robinson, New York, radiology
- Dr. Georgiana M. Dvorak, Theobald, Oak Park, Ill., medicine
- Dr. Owen H. Wangenstein, Minneapolis, surgery
- Dr. Meyer Wiener, St. Louis, ophthalmology

VIRGINIA

Health Department Activities—Halifax and Pittsylvania counties have been consolidated under the supervision of Dr. Daniel C. Steelsmith and will be known as the Halifax-Pittsylvania Health District, with headquarters at South Boston.—Dr. Marvin E. McRae, Chatham, health officer of Pittsylvania County, succeeds Dr. Samuel S. Shouse, Luray, health officer of the Page-Warren-Shenandoah Health District. The latter was granted a leave of absence to enter military service. Dr. James A. Dolce, U. S. Public Health Service, Washington, D. C., has been appointed health officer of the Fairfax-Prince William-Stafford Health District, succeeding Dr. Clifford E. Waller, Leesburg, who remains as health officer of Loudoun County with headquarters at Leesburg. Loudoun County was formerly a unit in the health district.

GENERAL

Southern Surgical Cancels Meeting—The Southern Surgical Association has canceled its annual meeting which was to be held in Savannah, Ga., December 8-10.

New Abstracts of Food and Nutrition Research—*Biological Abstracts* announces the establishment of a new (seventh) section, "Specially Assembled Abstracts of Food and Nutrition Research," to be initiated in January 1943. The section will consist of an assembly and reprinting of all the abstracts contained in *Biological Abstracts* that deal with foods and nutrition. Each volume will consist of ten abstract issues, subscribers will receive the index to the complete edition of *Biological Abstracts*. The subscription price will be \$6 a year (plus 50 cents for postage outside the United States). Inquiries should be addressed to *Biological Abstracts*, University of Pennsylvania Philadelphia.

Sigma Xi Lecturers—The Society of the Sigma Xi, national honor society for the promotion of scientific research, has announced its national lecturers for 1943. Two of the five lecturers are Detler W. Bronk, Ph.D., professor of neurology at the University of Pennsylvania School of Medicine, Philadelphia and Conrad A. Elvehjem, Ph.D., professor of agricultural chemistry, University of Wisconsin, Madison, Wis. on "Physical Structure and Biological Action of Nerve Cells" and "The Present Status of the Vitamin B Complex" respectively. The lectures will be delivered before special meetings at universities and colleges throughout the country during January, February, March and April, the dates and places to be announced later.

Fellowships Awarded—The Lalor Foundation announces the award of its sixth annual series of fellowships to:

A. Calvin Bratton, University of Texas, Austin, to work with Dr. E. H. Marshall Jr. at Johns Hopkins University School of Medicine, Baltimore.

Edward H. Frieden, University of California, Berkeley, to work with Roger J. Williams, Ph.D., at the University of Texas.

Francis J. Reithel, University of Oregon, Eugene, to work with Edward A. Doisy, Ph.D., at the St. Louis University School of Medicine, St. Louis.

James R. Weisger, Johns Hopkins University, to work with Albert Baird Hastings, Ph.D., at Harvard Medical School, Boston.

The work of the recipients is in fields closely related with problems of the war. Owing to war conditions appointments to the five remaining fellowships originally scheduled for the 1942-1943 series have been postponed. The foundation also announces that its present plan is to discontinue its regular program of fellowship awards until the demobilization of scientific personnel at the end of the war. Thus it is planned that the usual fellowship awards of the foundation will go into a reserve to form an accumulation for postwar assignment. To date fifteen such awards have been scheduled to be made available at that time for postdoctorate research in chemistry. The standard annual stipend of a Lalor Foundation award is \$2,000.

Dr Winslow Receives Sedgwick Medal—Charles-Edward A. Winslow, Dr. P.H., Anna M. R. Lauder professor of public health at Yale University School of Medicine, New Haven, Conn., since 1915, was awarded the William Thompson Sedgwick Memorial Medal during the annual meeting of the American Public Health Association in St. Louis, October 27. The medal is for distinguished service in public health and was presented by Dr. Haven Emerson, New York, 1935 winner of the award. Dr. Winslow received his degree of doctor of public health at New York University in 1918 and began his career in public health as assistant health officer of Montclair, N. J., in 1898, subsequently serving on the staffs of the Massachusetts Institute of Technology, Boston, University of Chicago, and the College of the City of New York, from 1910 to 1922 he served as curator of public health at the American Museum of Natural History, New York. For one year, 1914-1915, he was director of the division of public health education of the New York State Department of Health. He formerly served as a member of the board of scientific directors of the International Health Division of the Rockefeller Foundation and president of the American Public Health Association. He has been editor-in-chief of the *Journal of Bacteriology* since 1916.

Supreme Court Asked to Declare Unconstitutional Contraceptive Legislation—About seven hundred physicians throughout the United States filed briefs in support of a petition asking the U. S. supreme court to review a decision by the Connecticut Supreme Court of Appeals holding legislation which prohibits physicians from prescribing contraceptive devices for married women when necessary to preserve life or health as constitutional. The physicians' briefs supported a

petition of Dr. Wilder Tileston, David P. Smith, clinical professor of medicine at Yale University School of Medicine, New Haven, and a practicing physician. According to the *Washington Star*, October 25, Dr. Tileston started the litigation by requesting an opinion as to whether the statute would prohibit him from prescribing contraceptives to three specified patients. A brief filed by one hundred and sixty-six physicians in thirty-six states and the District of Columbia contended that "medical opinion with substantial unanimity supports the prescription and use of contraceptives in cases" like those involved the *Star* stated. Another brief presented by five hundred and forty-one Connecticut physicians asserted that Dr. Tileston was "faced with the alternative of failing in his duty as a physician or subjecting himself to a criminal penalty in the event that this statute is found to be constitutional" (*THE JOURNAL*, July 4, p. 817).

Special Society Elections—Dr. Lawrence T. Post, St. Louis, was chosen president elect of the American Academy of Ophthalmology and Otolaryngology during its annual session in Chicago, October 13, to take office Jan. 1, 1944, and Dr. James A. Babbitt, Philadelphia, will take office as president Jan. 1, 1943. Vice presidents are Drs. Sanford R. Gifford, Chicago, Wesley C. Bowles, New York, and William A. Krieger, Poughkeepsie, N. Y. Dr. William L. Benedict, Rochester, Minn., was elected executive secretary to succeed the late Dr. William P. Wherry, Omaha.—Dr. Lewis F. Smead, Toledo, Ohio, was chosen president elect of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons recently and Dr. Willard R. Cooke, Galveston, Texas, was installed as president. Dr. James R. Bloss, Huntington, W. Va., is the secretary. The Homestead, Hot Springs, Va., was designated as the place for the next annual session, Sept. 9-11, 1943.—Dr. Sherwood Moore, St. Louis, was chosen president elect of the American Roentgen Ray Society at its recent annual session and Dr. Ralph S. Bromer, Bryn Mawr, Pa., was installed as president. Dr. H. Dabney Kerr, Iowa City, is the secretary.—Dr. Fred B. Moor, Los Angeles, was elected president of the American Congress of Physical Therapy at its annual meeting in September, succeeding Dr. Abraham R. Hollender, Miami Beach, Fla. Other officers include the following vice presidents, Drs. Kristian G. Hansson, New York; Miland E. Knapp, Minneapolis; Walter S. McClellan, Saratoga Springs, N. Y.; Herbert W. Kendall, Dayton, Ohio; and Kenneth Phillips, Miami, Fla. Dr. Richard Kovacs, New York, secretary and Dr. John S. Coulter, Chicago, treasurer. In recognition of distinguished services to the science of physical therapy, gold key awards were made by the congress to President Roosevelt, Bernard M. Baruch, LL.D., New York; Dr. William Bierman, New York; and Dr. William S. C. Copenman, London.

CANADA

Memorial to the Late Dr. Thomas Gibson—A number of old medical books have been donated to the library by graduates of Queen's University Faculty of Medicine, Kingston, with the suggestion that they form the nucleus of a special library of medical history to serve as a memorial to the late Dr. Thomas Gibson who for a number of years served as professor of pharmacology and therapeutics and at the time of his death was professor of the history of medicine at the university. It is hoped that other contributions will be made by alumni and friends to help toward the building of a comprehensive collection of textbooks to honor Dr. Gibson.

LATIN AMERICA

Personal—Dr. Gregorio Araoz Alfaro, Buenos Aires, recently celebrated his fiftieth anniversary in the practice of medicine, when a special ceremony was held by the dean and members of the Faculty of Medicine of Buenos Aires and of the Academy of Medicine. A celebration was also held at the Instituto de Semilogia y Clinica Propedeutica del Hospital de Clinicas of Buenos Aires to unveil a plaque in honor of Dr. Alfaro.—Dr. Moreira da Fonseca of Rio de Janeiro, professor in the chair of tropical diseases of the Faculdade Nacional de Medicina, Rio de Janeiro, was appointed president of the Academia Nacional de Medicina to fill the vacancy left by Dr. Carlos Chagas who died Nov. 8, 1934.—Dr. Aquiles S. Lentino of the Instituto de Clinica Quirurgica de Buenos Aires was given the first scholarship of the Arce Foundation of Buenos Aires. The scholarship of \$2,200 a year is for studies in the United States. Dr. Lentino began use of the scholarship in October in the Barnes Hospital, St. Louis, working under the guidance of Dr. Evarts A. Graham.

LONDON

(From Our Regular Correspondent)

Oct 10, 1942

Germany's Lack of Doctors The Nazi Conception of "Public Health"

The *Times* states that Germany is now facing a lack of doctors, nurses and hospitals. Since 1933 the number of medical students has dropped by half. The elimination of Jewish physicians caused a considerable reduction of medical personnel. Then came unforeseen demands on the eastern front. According to official admissions, where previously German civilians had one doctor for every two thousand people they have now only one for every twelve or fifteen thousand. The coming winter is likely to increase the need for medical services both at home and in the field. Hitler has appointed Professor Dr Brandt to be commissary general for medical and health services to act as liaison between the military and civilian sectors and to receive orders direct from him. He has thus once again shortcircuited the normal state administrative services. He continues to develop the administration that he has declared he desires—men who will override all precedents and precepts and act according to the need of the hour. Brandt will pass Hitler's decisions to General Oberarzt Professor Doktor Handloser, chief of the army medical service, on the one hand and to Dr Conti, reich health leader, on the other. It is stated in the British press that measures objectionable even to the German people have been taken by the puppet controllers of "a new hygiene." Their notion of "the people's health" is in conflict with the ideals of Western civilization. The "health" of the nation is to be promoted by elimination of the weak. Hence the campaign of "mercy death," the systematic murder of the inmates of asylums and nursing homes. Hence also the propaganda that every woman who bears a child to a German soldier, whether married or not, is fulfilling a patriotic duty. The organ of the notorious S S, "das schwarze corps" aims at the compulsory dissolution of childless marriages and the compulsory production of children at least by every married couple, if not by every able bodied man and woman. The S S has become the ruling power both in Germany and in occupied Europe. Its tyranny controls everything even matters of public health.

Good Health of United States Troops in Britain

Brig Gen Paul R Hawley, chief medical officer of the United States Army in Europe, has stated that the sick rate among American troops in Great Britain has for the past six months been below that of the troops in the United States. This was chiefly due to the men over here having been conditioned by at least one year's service the sick rate being naturally higher among recruits. But he looked forward to the winter with some apprehension because the English winters were not to the liking of Americans and they had to get acclimatized. He expected, for instance many colds, and precautions were being taken such as providing drying facilities so that men should not have to put on wet clothing. Different countries had different breeds of germs, and Americans in a strange country were not immune from them. In the conditions of today it was necessary to have light surgical teams that could go very far forward and thus take assistance to casualties who might not be transported to base hospitals for several days. These teams would consist of three doctors a nurse and one or two soldiers, and their equipment would be carried by ordinary transport.

Food in Powder and in Blocks

Since the outbreak of the war the Ministry of Food which controls everything connected with food—its production importation storage and rationing—has followed the policy that, in spite of many restrictions every one should have sufficient for the maintenance of health and strength. It has neglected no means of ensuring adequate rations and thus has contributed to our fighting strength. Home production of food has been enormously increased in order to save shipping for war purposes. Another measure was to reduce the bulk of imported products while maintaining their food value by eliminating water. This requirement has been met by work carried out at the Low Temperature Research Station, Cambridge in cooperation with other institutions here and in the United States and the dominions. It is estimated that dehydration has saved shipping to the extent of 3,000,000 tons of water annually. A quart of milk has a volume of 69 cubic inches and weighs 41 ounces. Condensed it has a volume of 27 cubic inches and weighs 16 $\frac{1}{10}$ ounces. Reduced to a powder it has a volume of 15 $\frac{1}{10}$ cubic inches and weighs 5 $\frac{3}{10}$ ounces. With the powder compressed into a block the volume is further reduced to 7 $\frac{7}{10}$ cubic inches. This discovery makes possible the preservation of rich spring and early summer milk for winter use.

Next year we shall import 100,000 tons of dried egg the equivalent importation of egg in shell would amount to more than 500,000 tons and more than six times the shipping space. A similar saving is made by importation of dried meat. Another advantage is that dried egg and meat do not require refrigeration for transport or storing. Scientists here and in the dominions have cooperated to produce a method of shipping and storing butter without refrigeration. Butter consists of fat 82.5 per cent, water 16 per cent, milk solids 5 per cent and salt 1 per cent. Being perishable it has to be frozen for transport and storage. By removing the water and nonfatty solids, a pure dry butterfat is obtained, which is relatively nonperishable, is not spoiled by microbes and will keep for months without refrigeration. Most of the nutritive value of butter lies in its calorific property, and the vitamins A and D are in the fat. In New Zealand and Australia butterfat is prepared by melting the butter and removing the water and fat by centrifugation. Here the butter can be reconstituted by churning in water, separated milk powder and salt. Summer butter, which has a higher nutritive value than winter, can thus be stored for winter use.

Meat, fish, spinach, onions and other foods can thus be reduced to hard blocks, which, when reconstituted by adding water and cooked, are indistinguishable from fresh food. These products have been found very useful for transport by the fighting forces, and the men like the food prepared from them. Trials have shown that they get more vitamin C from dried than from fresh cabbage. Though the war has brought about this new development, its advantages are so obvious that it must mark a permanent advance in our methods of dealing with food. Thus dried cabbage can be used in the dark winter months when fresh vegetables are scarce. Great care has been taken to ensure that the full nutritive value of dried foods is retained and in general so also is their palatability.

A Nutrition Council Postwar Relief of the Devastated Countries

The production and consumption of food during the war has been controlled by the government. The *Times* makes the proposal, which has received eminent medical support, that a nutrition council should be established to undertake systematically the work now done by a great number of committees and other authorities without any common plan or effective coordination. The council undertaking this work would con-

duct a continuous review of the state of nutrition in all the different sections of the population, ascertain where and in what respects it is satisfactory or deficient and advise the Ministry of Food on questions of diet. To obtain the greatest benefit from the organization which has been created and steadily improved during the war to provide and distribute as fairly as possible the food we need, it is essential to know what these needs are. We have rationing and price control but these are only the final stages of operations extending over a wide field agreements with the other countries, notably with the United States and the dominions, the stocking and storing of reserves and the control of home production, which now provides a much greater proportion of our food than would have been thought possible before the war. After three years, during which many of our principal sources of supply have passed under enemy control and our shipping has been attacked we remain the best fed country in Europe. The work of the Ministries of Food and of Agriculture has been a definite success.

This machinery, created to meet the needs of war cannot be allowed to lapse when peace is declared. There will be an uneasy transition period perhaps for some years, before the nations can rely on an international economic system working with even tolerable smoothness. During that time shipments will have to be controlled to ensure the supply of necessary foods, and rationing will have to be maintained. To allow the use of the limited amount of shipping and foreign exchange available to be determined by the competition of importers guided solely by the profit motive and the price mechanism would impose intolerable strains on our shipping resources and the stability of the currency. Moreover the governments of the United Nations have responsibilities, which they do not wish to evade, toward the peoples of the occupied, looted and devastated countries. The duty of providing immediate relief as soon as the despoiler has been expelled has not been recognized only in words. Committees have been appointed to make the necessary arrangements to avoid disastrous delays, and large quantities of grain have been set aside for the purpose.

Hospital Priority for War Workers

There is a drive for war efficiency at Guy's Hospital. In the outpatient department the period of waiting to be seen which sometimes is long is shortened for war workers. When first seen in the front surgery a patient who is a war worker is given a distinguishing label which entitles him to be seen before all other patients excepting in acute emergencies. If he becomes an inpatient his stay in the hospital may not be prolonged for teaching purposes. Special measures have been taken to ensure that paronychia, injuries of the hand and the like which interfere with manual work receive expert treatment from the first. Thus there is a saving of man hours by shortening the period of disability. Previously the registrars may have been too busy with teaching to attend to such cases.

How Britain Has Stood the Air Raids

The calmness with which this country faces the greatest crisis in its history has been pointed out in previous letters. The absence of any disturbance of our mental poise is now shown by a report of Dr. Aubrey Lewis, clinical director and lecturer in psychiatry at the Maudsley Hospital, to the Medical Research Council, which has been published in the *Lancet*. An elaborate investigation of bombed areas throughout the country showed no striking increase in neurotic illnesses. Figures from hospitals and clinics suggested even a considerable drop. The impressions of good medical observers indicate a slight rise in neurotic illness after intensive raids, chiefly among those who have been neurotically ill before. Neurotic reactions may not

appear for a week or ten days after the bombing. They usually clear up readily under rest and mild sedatives. The commonest forms of upset are anxiety and depression, hysteria is uncommon. In fire fighters and other workers in civil defense, neuroses are low. The number of cases of insanity has not increased. In Scotland suicide has actually diminished, figures for England are not yet available. There is no increase of alcoholism. No doubt the large scale evacuation from cities to be out of the reach of air raids has played some part in the diminution of neuroses.

Increase in Industrial Accidents

In a discussion on "The Personal Factor in Accidents," the Medical Research Council reports a great increase in industrial accidents during the war. In factories alone there were 232,000 accidents, of which 1,384 were fatal, in 1940, an increase over the preceding year of 39,000 accidents and 280 fatalities. The figures for 1941 have not yet been published. What increase in the accident rate these figures represent has not been stated. The increase is due in part to the larger number of persons engaged in war work and in part to the inexperience of a great many of them. The increase in accidents is out of proportion to the increase of persons employed. There is a tendency in some quarters to accept the increase as part of the war effort and to say that, as our fighting men are taking every risk, civilians should not bother about safety. But the chief inspector of factories points out that those men are carefully trained not to take unnecessary risks.

The longer working hours of wartime may be partially mitigated by rest pauses, by change of occupation, by sitting when possible and by adjusting benches and machines to the worker, so that the whole of his energy can be directed to his work and not to overcoming discomfort and unnecessary hindrances. It is important to avoid extremes of heat and cold and to have adequate ventilation. Lighting may be a cause of accidents if it is so inadequate that the worker cannot see his work clearly or if there is glare.

On the question of proneness to accidents it is stated that the majority are sustained by a small minority of workers. To remove these from a dangerous occupation would be the most effective way of dealing with accidents. Psychologic tests have been used to discover workers who are a danger to themselves and to others under certain conditions. For the keeping of accident records the card index system, in which there is a card for each worker, whether he has had an accident or not, is recommended. The best method for reducing accidents due to proneness would be to use tests supplemented by the record of all accidents during an initial period, for every occupation in which there is special risk.

Prophylactic Tetanus Antitoxin for All Battle Casualties

The War Office has reminded medical officers that antitoxin should be given to all battle casualties, even though they have had tetanus toxoid in the past or tetanus antitoxin recently. It should also be given to patients suffering from any wound that seems likely to be infected with tetanus. When given subcutaneously the maximum level in the blood is not reached for three or four days, but by deep intramuscular injection the same level is reached much more rapidly. Deep injection into the deltoid, subscapular or outer quadrant of the gluteal regions should be the normal route. Intravenous injection is not recommended for prophylaxis because of the possibility of anaphylaxis. The minimum dose should be 3,000 units. For very foul lacerated wounds, this should be doubled or tripled. If there is documentary evidence of active immunization with toxoid, a single dose of antitoxin is sufficient. Otherwise two further doses of 3,000 units should be given at weekly intervals.

Sulfanilamide Therapy by Transthoracic Injection

Dr. Mariano R. Casten, head of the First Medical Clinic of the Faculty of Medicine of Buenos Aires, lectured in the Academia Nacional de Medicina of Buenos Aires. He reported the results of transthoracic intrapulmonary sulfanilamide injections, which he has employed in collaboration with Dr. Eduardo L. Crapdelourat in the treatment of diffuse bronchopulmonary suppuration. The method is indicated in exceptionally rare cases. The authors observed that pulmonary suppuration which is not controlled by classic medical therapy is cured by nebulizations with sulfanilamide except in about 15 per cent of the cases, which are cured by transthoracic intrapulmonary sulfanilamide injections. The authors have resorted to this method for about one year in a group of 25 patients with bronchopulmonary suppuration of various types and for some patients with pulmonary tuberculosis with cavitation. The total number of injections of sulfanilamide and other substances administered to the group is about five hundred. The method of intrapulmonary injections of sulfanilamide is not a substitute for sulfanilamide nebulizations. The injections are administered during the acute period of suppuration, after which they are discontinued and nebulizations are given. At first, the authors used azosulfamide. Later on they used soluseptasine (a benzyl-sulfanilamide derivative), sulfathiazole or alcohol with azosulfamide. All drugs to be used by the intrapulmonary route should be well tolerated when they are intravenously administered. Transthoracic intrapulmonary sulfanilamide injections are indicated in acute suppuration of the whole pulmonary lobe or in suppuration with diffusion to the whole lung in which the clinical therapy fails and an operation is contraindicated. The method is contraindicated in cases of suppuration which is circumscribed to small zones of a lobe as well as in cases of suppuration in or near the hilar region (because of the danger of injuring the large vessels or nerves) and also in suppuration in zones near the heart and its vessels. The procedure, if performed properly, is not complicated by hemorrhage or by the spreading of the infection. Acute spasmodic cough and sometimes apnea appear immediately after the injection, then spontaneously and rapidly disappear. Bronchovesicular and bronchopulmonary reflexes can be prevented by giving a subcutaneous injection of neutral atropine sulfate fifteen minutes before the transthoracic injection. As soon as the liquid comes in contact with the pulmonary parenchyma a local burning pain is felt which spreads to the back and the neck and lasts for several hours or up to the following day. The body temperature rises to 104 F and then subsides to normal. The injection does not provoke or increase dyspnea and cyanosis. In the larger number of cases twenty treatments with two injections for each treatment control the acute phase of the disease, after which the injections are discontinued and the nebulizations and other proper procedures are employed. The authors advise using this method in the treatment of other pulmonary conditions, such as gangrene of the lung.

Crusade Against Cancer

The center Seccion de Neoplasias of the National Department of Hygiene was recently organized to carry on the necessary work for an early diagnosis of cancer, to establish in the country several centers for work against cancer, to stimulate research on cancer and to educate and advise the people on how to work and live in order to avoid the danger of cancerogenic substances (tar, paraffin, anthracene, carbon monoxide and tobacco). The center will prepare statistics of morbidity

and mortality from cancer and will prohibit the sale of the so called specifics against cancer. The Seccion Neoplasias will organize a special department for biopsy and histopathologic examinations. Patients who are sent by physicians from remote provinces will receive immediate attention. There will be collaborating committees all through the country. Children of hospitalized parents will be cared for by persons appointed by the center as long as the parents need hospitalization.

Congress of Sanitation and Social Medicine

The second Argentine Congress of Sanitation and Social Medicine was held in Buenos Aires, July 8-11, under the auspices of the Federacion Medica of Argentina. Dr. Victorio Monteverde is the president of the federation. The topics discussed were general sanitation and social medicine in the country. The reports presented were based on statistics of morbidity, mortality, infant mortality, regional diseases and regional mortality and mortality from infectious and contagious diseases in relation to sanitation. In preparing these reports special attention was given to the information from physicians who live in rural zones. There were also discussions on food and housing.

National Formulary in Peru

The minister of public health recently passed a law through which the national formulary of Peru will be edited. The Comision Inspector de Farmacias is in charge of editing the book. The members of the editorial committee are authorized to ask for the collaboration of the national institutions and technical national centers whenever they consider it advisable.

Clinical Laboratories in Chile

A law was recently passed in Chile by which chemical biologic, serologic, citologic and histopathologic laboratories, either for private groups or for centers of public services must have a license from the General Department of Public Health and the head and personnel of the laboratories are required to have a certificate of competence.

One Woman Physician in Peru

There is only one woman physician in Peru. Dr. Mercedes Cisneros, who practices in Lima, whereas in Chile there is an Asociacion Medica Femenina with three hundred members.

Marriages

PRENTISS McLEOD KINLEY to Miss Mary Adelaide Smith both of Bennettsville, S. C., in Battle Creek, Mich., recently.

EUSTON SPENCER ROBERTSON, Arlington, N. J., to Miss Elizabeth Tinsley of Bayonne at Tampa, Fla., July 29.

AUDREY JANE McDONALD Roodhouse, Ill., to Mr. James M. Ballowe of Chicago in Compton, Calif., September 18.

JAMES ODELL FIELDS to Miss Cecile Marie Williams both of Milan, Tenn., at Corinth, Miss., August 29.

HERBERT CARLYLE SANDERSON, Vallejo, Calif., to Miss Gladys Louise Barton at San Francisco, August 28.

JOHN FRANKLIN REYNOLDS Waterville, Maine, to Miss Jane Ann Loughland of Minneapolis, April 11.

RALPH VICTOR ELLIS to DR. ELIZABETH GREASON HUNTER LANGE, both of Minneapolis, August 31.

THOMAS MILTON MARSHALL, Frankfort, Ky., to Miss Nancy Miller of Hardinsburg, August 8.

CARL M. AUSTIN, Dallas, Texas, to Miss Lu Eva Sullivan of Mangum, Okla., August 12.

CLIFFORD B. COLE, Norman, Okla., to Miss Janice L. Beaghtler in Yuma, Ariz., July 25.

GARVIN G. GOBLE to Miss Margaret Dinsmore, both of San Francisco, July 25.

DANIEL B. CORWIN to Miss Bella Beresofsky, both of New York, August 1.

Deaths

Allen Greenwood * Boston, Harvard Medical School, Boston, 1889, professor of ophthalmology emeritus at the Tufts College Medical School, for many years lecturer on ophthalmology at the Harvard Medical School, Courses for Graduates assistant instructor in ophthalmology at his alma mater, 1904-1905, member of the American Board of Ophthalmology, chairman of the Section on Ophthalmology of the American Medical Association, 1919-1920, member and past president of the American Academy of Ophthalmology and Otolaryngology the New England Ophthalmological Society and the American Ophthalmological Society, member of the Association for Research in Ophthalmology, Inc. fellow of the American College of Surgeons, veteran of the Spanish-American War, during World War I served in the Royal Army Medical Corps as an honorary lieutenant colonel with the British Expeditionary Forces in France, as a major and lieutenant colonel in the medical reserve corps of the U S Army, in the Surgeon General's Office at Washington, D C, and as senior consultant in ophthalmology for the American Expeditionary Forces, received a citation from Gen John J Pershing for meritorious and conspicuous service, colonel in the medical reserve corps of the U S Army member of the subcommittee on ophthalmology, general medical board, Council on National Defense, in 1917, bacteriologist for the board of health of Waltham, Mass, from 1894 to 1898 at one time special examiner for the U S Pension Bureau, consulting ophthalmic surgeon to the Massachusetts Eye and Ear Infirmary Boston City and Beth Israel hospitals Boston the Milford (Mass) Hospital and the Union Hospital, Frammingham visiting ophthalmic and aural surgeon Waltham (Mass) Hospital, aged 76 died October 23 in Miami Fla

John Albert Robison * Chicago Rush Medical College Chicago 1880, an Affiliate Fellow of the American Medical Association and member of the House of Delegates in 1912 formerly assistant professor of medicine at his alma mater past president of the Illinois State Board of Health chairman examining committee department of registration and education of Illinois for many years, organized the Chicago Society of Internal Medicine in 1901, president of the Chicago Medical Society, 1909-1910 chairman of the committee on publication in 1886 and a founder of the *Chicago Medical Record* which published the society's proceedings for several years served as a major in the medical reserve corps of the U S Army during World War I attending physician, Central Free Dispensary, from 1880 to 1888 member of the staff of the Cook County Hospital from 1884 to 1892 formerly consulting physician to St Joseph's Hospital on the consulting staff and for many years attending physician and secretary of the medical board of the Presbyterian Hospital, where he died October 18, of pneumonia aged 87

Samuel Poindexter Oast * New York, University of Pennsylvania School of Medicine, Philadelphia, 1911, specialist certified by the American Board of Ophthalmology, assistant clinical professor of ophthalmology at the New York University College of Medicine, member of the American Academy of Ophthalmology and Otolaryngology and the American Ophthalmological Society served during World War I, at one time associated with the U S Public Health Service, formerly ophthalmic surgeon to the New York Eye and Ear Infirmary and consulting ophthalmologist, U S Marine Hospital, aged 55, died, October 16, in Portsmouth, Va

Edmund Louis Gros, West Chester, Pa, Cooper Medical College, San Francisco, 1891, for many years chief of the American Hospital in Neuilly, France, an organizer of the Lafayette Flying Corps and Escadrille, famous organization of American volunteers in French aviation service, for his service to France was admitted to the French Legion of Honor, in 1919 was created Officer, for services with Liaison Section, Air Service, American Expeditionary Forces in 1929 was made a Grand Officer of the Royal Order of Saint Sava by the late King Alexander of Yugoslavia, aged 73, died, October 16

Isidor Mack Unger * Ithaca, N Y, Bellevue Hospital Medical College, New York, 1898, past president of the Tompkins County Medical Society, veteran of the Spanish-American War and World War I chairman of the Tompkins County Citizens Military Training Camp, consultant Tompkins County Memorial Hospital, visiting physician, Cornell University Infirmary, colonel medical officers reserve corps U S Army, chairman of the Five County Medical Advisory Board number 41 New York Selective Service, aged 65, died, October 20

James Augustine Cahiff Jr * Washington, D C, Georgetown University School of Medicine, Washington, 1915, professor and head of the department of surgery at his alma mater since 1933, specialist certified by the American Board of Surgery served as a captain with the American Expeditionary Forces during World War I, consulting surgeon to the U S Public Health Service, chief surgeon at the Georgetown and Providence hospitals, consulting surgeon at the Columbia and Gallinger hospitals, aged 49, died, October 19

William Hall Coon, Easton, Conn, Bellevue Hospital Medical College New York, 1897, member of the Connecticut State Medical Society, at one time health officer of Easton, Bridgeport, Conn, and Kansas City Mo formerly representative in the state legislature and author of a bill establishing a commission, of which he was a member, to study the treatment and care of persons afflicted with mental or physical disabilities, veteran of the Spanish-American War, aged 67, died, September 30 of coronary thrombosis

Charles Daniel Price, Whitesboro, Texas, Vanderbilt University School of Medicine, Nashville, Tenn, 1908, member of the State Medical Association of Texas, past president of the Grayson County Medical Society, served for many years as a member of the board of education and as city health officer, for many years local surgeon for the Texas and Pacific Railway aged 64 died, August 28, of pneumonia

Lawrence Frank Eder * Santa Barbara, Calif, University of Minnesota Medical School, Minneapolis, 1924, president of the Santa Barbara County Medical Society, fellow of the American College of Surgeons, attending gynecologist and obstetrician Santa Barbara Cottage, Santa Barbara General and St Francis hospitals, affiliated with the Santa Barbara Clinic aged 42, died, October 11, of pneumonia

Samuel Jones Mattison * Pasadena, Calif, Northwestern University Medical School Chicago, 1904, fellow of the American College of Surgeons, served overseas as a captain in the medical corps of the U S Army during World War I, on the staff of the Collis P and Howard Huntington Memorial Hospital and St Luke Hospital, aged 67, died, October 3, of arteriosclerosis and cerebral hemorrhage

Harold Campbell Parsons, Toronto, Ont, Canada, Trinity Medical College Toronto 1892 M R C P, England 1906 served with the Canadian Army Medical Corps during World War I director of the chest clinics at the Toronto General Hospital and the hospital for Sick Children formerly consultant on the staff of the director of medical services for Canada aged 73 died October 15

Gilbert Random Finch, Centerpoint, Ind, Medical College of Ohio Cincinnati 1897, member of the Indiana State Medical Association, formerly served as county health officer and as secretary of the board of health of Centerpoint served during World War I, aged 76, died, October 19, in the Clay County Hospital, Brazil, of cardiovascular renal disease

James Hamlin MacIvor * Port Jefferson N Y, New York Homeopathic Medical College and Hospital New York 1892, president of the medical board and chief of the staff of internal medicine at the John T Mather Memorial Hospital, aged 70, died, October 15, in the Flower and Fifth Avenue Hospitals New York

William Northam Trader, Sonoma, N Y University of Virginia Department of Medicine, Charlottesville 1904, member of the Medical Society of the State of New York and the American Psychiatric Association, assistant medical superintendent of the Crug Colony, aged 65, died, October 11, of coronary thrombosis

Elizabeth Anne Bergner * Chicago, Rush Medical College, Chicago, 1930, on the staffs of the Swedish Covenant and Children's Memorial hospitals, formerly on the visiting staff of the Lewis Memorial Maternity Hospital aged 46, died, October 26, in the Albert Merritt Billings Hospital of hepatitis

Michael James McMahon, Buffalo, University of Buffalo School of Medicine 1910, member of the Medical Society of the State of New York, served during World War I, on the staffs of the Mercy Hospital, Buffalo, and Our Lady of Victory Hospital, Lackawanna, aged 53, died, October 5

Waverly Stafford Tucker, Newark, N J, Medical College of Virginia, Richmond 1915, served in France with the American Expeditionary Forces during World War I, on the staffs of the Hospital of St Barnabas and St Michael's Hospital, aged 52, died, October 9

Hugh Hill Dorr * Columbus, Ohio, Starling-Ohio Medical College, Columbus 1909, chief medical examiner of the division of claims, state industrial commission, at one time on the staff

of the Athens (Ohio) State Hospital, aged 57, died, October 1, in the Mount Carmel Hospital

Eugene E Woodruff, Cooper, Texas, Memphis (Tenn) Hospital Medical College, 1901, formerly a lawyer, member of the State Medical Association of Texas, past president of the Delta County Medical Society, aged 69, died suddenly, August 24, of heart disease

Henry Wade Hopkins ♂ Warren, R. I., University of Vermont College of Medicine, Burlington, 1902 organized and directed the medical division of the Warren civilian defense council, aged 67, died suddenly, October 14, in Burlington, Vt., of cerebral hemorrhage

Vellora Meek Henry, New Wilmington, Pa., Medical College of Ohio, Cincinnati, 1879, for many years a medical missionary in Assiut, Egypt, aged 88, died, October 3, of uremia and chronic interstitial nephritis in the Shadyside Hospital, Pittsburgh

Homer Samuel Warren Jr, Chicago, University of Illinois College of Medicine, Chicago, 1922, member of the Illinois State Medical Society, aged 51, past president of the American Hospital, where he died, October 18, of carcinoma following x-ray burns

James Clark Bennett Jr, Yonkers N. Y., University of Pennsylvania Department of Medicine, Philadelphia 1890, also a lawyer, author of "Shedding the Years", aged 76, died, October 10, in St. John's Riverside Hospital of carcinoma of the colon

Clarence Araville Hercules, Harvey, Ill., Northwestern University Medical School, Chicago, 1904, member of the Illinois State Medical Society, on the staff of the Cook County Infirmary, Oak Forest, for many years, aged 64, died, October 24

David Newton Blakely ♂ Boston, Dartmouth Medical School, Hanover, N. H., 1896, assistant medical director of the New England Mutual Life Insurance Company, aged 75, died, October 15, of coronary thrombosis at his home in Brookline

William Haley Kirk, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1891, member of the Medical Society of the State of Pennsylvania for many years on the staff of St. Joseph's Hospital, aged 71, died, October 12

William Carroll Barnett, Big Spring, Texas, St. Louis College of Physicians and Surgeons, 1893, served as county health officer for many years and as county treasurer from 1903 to 1906, aged 70, died, August 2, in a hospital at Dallas

John Patrick Crotty, East St. Louis, Ill., St. Louis University School of Medicine 1934, at one time physician for the school board of East St. Louis, formerly district health officer, aged 33, died, October 8, at Tucson, Ariz.

John Q Taylor, Paducah, Ky., University of Louisville (Ky.) Medical Department, 1883, consulting surgeon and formerly assistant chief surgeon at the Illinois Central Hospital, aged 89, died, September 24, of arteriosclerosis

Martha Elma Osmond ♂ Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1898, physician at the Bryn Mawr College from 1899 to 1903, aged 79, died, October 15, of aortic and mitral insufficiency

Arnold H Johnson, Binghamton, N. Y., Long Island College Hospital, Brooklyn, 1919, member of the Medical Society of the State of New York, aged 46, died, October 9, in the Binghamton City Hospital

William Robert Bennett, San Antonio, Texas, Fort Worth School of Medicine, Medical Department of Fort Worth University, 1900, member of the State Medical Association of Texas, aged 69, died, October 15

Charles W Meckstroth, Brandon, Minn., University of Minnesota College of Medicine and Surgery, Minneapolis, 1895, for many years postmaster of Brandon and member of the school board, aged 70, died, October 4

George Bancroft Maxwell ♂ Davenport, Iowa, Rush Medical College, Chicago, 1888, aged 77, on the staffs of St. Luke's Hospital and the Mercy Hospital, where he died, October 14, of uremia

Alphons John Reiner, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1904, aged 62, on the staff of the Lankenau Hospital, where he died, October 4, of coronary occlusion

Isaac Walter Lytle ♂ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia 1895, on the staffs of the Lankenau, Wills and St. Joseph's hospitals, aged 74, died, October 18

Warren John Peters ♂ Allentown, Pa., University of Pennsylvania School of Medicine Philadelphia, 1918, on the staffs of the Allentown and Sacred Heart hospitals, aged 50, died September 27

Luella Mary Masters, Thorntown Ind., Syracuse University College of Medicine 1891, formerly a medical missionary in China, aged 81, died, October 7, in the Witham Memorial Hospital, Lebanon

Ruth Hilliard, Newark N. J., Hahnemann Medical College and Hospital, Chicago 1907, superintendent of the Essex County Parental School, aged 38, died October 10, of uremia and encephalitis

Delia Lucretia Chapin, Springfield Mass., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890, member of the Massachusetts Medical Society, aged 88, died, October 7

Channing Elmer Wolfe ♂ Coon Rapids Iowa, Northwestern University Medical School, Chicago, 1903, past president of the Carroll County Medical Society, aged 64, died, September 17

Sara Meltzer, Winnipeg, Man. Canada, University of Manitoba Faculty of Medicine, Winnipeg 1924, aged 42, died, October 11, in the Winnipeg General Hospital of carcinoma of the breast

Charles Joseph Overman ♂ Marion, Ind., Medical College of Indiana, Indianapolis, 1896, on the staff of the Marion General Hospital, aged 76, died, October 3, of coronary thrombosis

Earle A Mowry ♂ Mexico N. Y., Syracuse University College of Medicine 1904, mayor of Mexico, past president of the board of education, aged 66, died, October 12, of coronary thrombosis

Casper Frank Melcher, South Bloomingville Ohio, Eclectic Medical Institute, Cincinnati, 1895, aged 74, died September 30, in the Cherrington Hospital, Logan, of coronary thrombosis

Edward H Bird, Dupont, Ohio, Columbus Medical College 1887, member of the Ohio State Medical Association, aged 80, died, October 14, in the Lima (Ohio) Memorial Hospital

Samuel Traner Buck, Philadelphia, Medico-Chirurgical College of Philadelphia, 1890, aged 73, died, August 21, in the Lankenau Hospital of hypertensive cardiovascular renal disease

Charles W Stegmenn, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia 1902, on the staffs of the Frankford and Children's hospitals, aged 61, died October 4

Chester P Thompson ♂ Greenville, Miss., Chicago College of Medicine and Surgery, 1914, on the staff of the King's Daughters' Hospital, aged 63, died, October 15, of myocarditis

Vincent Frederick Keller, Chicago, Bennett Medical College, Chicago, 1913, aged 55, died, September 25, in the Veterans Administration Facility, Hines, Ill., of heart disease

Joseph Edward Walther, Rushville, Ind., Indiana University School of Medicine, Indianapolis 1912, member of the Indiana State Medical Association, aged 59, died August 28

Enoch E Long, Shoals, Ind., Louisville (Ky.) Medical College, 1897, member of the Indiana State Medical Association, coroner of Martin County, aged 73, died, September 23

Wallace Dickenson Wayne, Fayetteville, W. Va., University of Louisville (Ky.) Medical Department, 1921, member of the Arkansas Medical Society, aged 47, died October 8

Randall Jackson Weber, Philadelphia, Medical College of Virginia, Richmond, 1905, member of the Medical Society of the State of Pennsylvania, aged 63, died, September 5

DIED WHILE IN MILITARY SERVICE

William Henry Vail II, East Orange, N. J., Columbia University College of Physicians and Surgeons New York, 1939, in January 1942 was called to active duty as a first lieutenant in the medical reserve corps of the U. S. Army with St. Luke's Hospital Unit and was assigned to Fort Devens, Mass. in June was transferred to the Army Air Forces at Westover Mass., aged 32, was killed in an airplane accident near Blairstown September 19

Correspondence

THE CAMPAIGN AGAINST DIABETES

To the Editor—Your editorial of August 8 (*THE JOURNAL*, p. 1203) and the implication of its title, 'The Harmlessness of Glycosuria for a Patient Treated with Protamine Zinc Insulin' at once made me worry. Since its appearance my anxiety has increased for fear the view expressed would encourage patients and doctors to relax in their endeavor to fight diabetes tooth and nail.

For the belief which is in me I thank Naunyn, whose conception of diabetes I consider the best expression of the clinical wisdom of the past, and for the present I would cite the experimental evidence of Lukens and Dohan, which in a way is a culmination of that astute observation years ago of F. M. Allen recently evaluated, confirmed and further developed in England at the National Research Institute by Young in the University of Toronto by Best and his associates and in Philadelphia at the Cox Metabolic Institute.

The excerpt from Naunyn is rather long but I hope you will print it in full, because I do not think it has ever appeared in English, although brief references to it are frequent. My translation may be crude, but it errs on the side of being literal.

From Naunyn (*Der Diabetes Mellitus*, ed. 2, Vienna, Alfred Holder, 1906, pp. 390-391).

In many cases of diabetes glycosuria shows a decided tendency to progress. This can be the expression of the progress of a disease in an organ which is the cause of diabetes. For example, it is easily understandable in the case of the diabetes caused by pancreatic atrophy that, with the advancing degeneration of the organ, the glycosuria will become severer and ever more severe. There can further occur in the natural course of the disease even in pure diabetes without the existence of any disease of an organ as a cause of the metabolic anomaly, a progressive development for the worse and, as a sign of it, a steady increase of glycosuria. But in the majority of cases the progressiveness of the glycosuria is only the expression of the bad influence which the glycosuria itself exerts on the tolerance.

In its own time it is true the glycosuria will be determined by manifold external influences and above all in the first place, the responsibility for this rests on the nutrition—the diet.

A more exact discussion and foundation for these remarks has been given in the chapter on glycosuria and in other parts of this volume. On these grounds it follows that each severe glycosuria in a diabetic patient always ought to be prevented, because earlier or later it will become ominous where possible the glycosuria should be abolished on account of the favorable influence which the aglycosuric condition has on tolerance. Unconditionally this must be sought at the beginning of treatment, because in every case one must find out how much can be attained by this means.

"The desirability to commence to make the urine sugar free with such an experiment as the dietetic treatment of diabetes by which alone the glycosuria can be overcome with surety, today ought scarcely to be earnestly gainsaid. This must therefore be done, because otherwise the degree of the patient's existing tolerance for carbohydrate can be seriously affected. On this rests the decision as to whether the case is to be classified as mild or severe and, moreover, on it, above all, the diagnosis of the case depends.

"It is of paramount importance for incipient cases that the diabetes immediately at its first appearance be so energetically treated that if possible, the glycosuria will be abolished. I hold it from my experience very probable that among those early, strictly treated, cases which in the beginning impressed one as severe but later ran a favorable course, is many a one for which one can thank this early, strenuous treatment, and, furthermore, on the other hand there can be no doubt that in an overwhelming majority of the eventually severe, coursing cases are those which were subjected late if ever to energetic treatment. According to my view, one can with full justification talk about

a 'habitualization' of diabetes, of the diabetic glycosuria, in the same sense in which for years the term has been applied to the habitualization of other functional disturbances, especially those of nervous origin, for instance epilepsy, convulsions and neuralgia, irrespective of what the cause may be, these conditions gain in strength and become more difficult to overcome the longer they last.

The remarks made concerning laxity in dietetic therapy, however, must be somewhat more extensively emphasized because my point of view, based on the views first expressed, is today by no means universally accepted. I hold it for a pessimistic narrowing of the task laid on the physician in the treatment of diabetes if it is said that the essential task of the doctor is and remains to maintain the patient for a long time in an endurable condition of life. According to my point of view treatment includes a broader, more definite purpose, namely to strengthen (to improve) a disturbed function or at least to stop its further deterioration (the progressive development of the disease)."

My quotation from Lukens and Dohan is short, because the original article is easily available.

From Lukens and Dohan (*Endocrinology* 30:175 [Feb.] 1942).

In conclusion we have noted the fact that pancreatic lesions are produced by partial pancreatectomy or pituitary extract only in association with hyperglycemia. In like manner, the recovery of the islands is coincident with the return of the blood sugar to normal levels prior to irreversible damage to the islands, whether this is accomplished by insulin dietary treatment or phlorhizin. These findings support the hypothesis that the level of blood glucose is not only an index of the regulation of carbohydrate metabolism but also that it has, directly or indirectly, an influence on the islands of Langerhans. This influence is pathogenic when the blood sugar is high and beneficial when hyperglycemia is controlled, provided the lesions are not irreversible."

ELLIOTT P. JOSTIN, M.D., Boston.

"TOXICITY OF HUMAN PLASMA"

To the Editor—In your editorial "Toxicity of Human Plasma" (*THE JOURNAL*, September 19) reference is made to the case of severe reaction to lyophilized plasma reported by Polayes and Squillace (*ibid.*, March 28, p. 1050) and to work on dermal reactions to single type plasma performed by Levine and State (*Science* 96:68 [July 17] 1942). The former authors attributed the reaction in their case to a fairly high titer of isoagglutinin in the plasma, and the latter believed the principal cause of skin sensitivity was the agglutino-gen content.

Two objections may be raised to your summary of the suggested dangers. First, Levine and State's observations refer only to reactions of urticarial type, and no instance is reported of the important and really dangerous hemolytic reactions. Second, your last sentence, "since a negative skin test precludes the possibility of intravenous plasma shock," includes one assumption and one error, the assumption that this skin test-shock relation is really proved by the small group of observations reported and the error in calling the observed reactions "plasma shock." Levine and State reported the occurrence of headache, dyspnea, epigastric distress, chills, fever and urticaria, and in subsequent work (*THE JOURNAL*, September 26) indicate that relief of the symptoms was obtained by intramuscular injection of epinephrine. To call such symptoms "plasma shock" gives them an erroneous weight. This is not to deny that it is worth while to trace the allergens responsible for such reactions and if possible eliminate them.

Careful inquiry into the allergic history of the donor, bleeding donors only in the fasting state, and pooling are recommended by the Subcommittee on Blood Substitutes of the National Research Council especially with this objective in mind. Pyrogenic substances in aqueous solutions, tubing and apparatus must also be excluded.

Skin testing is a simple procedure, but interpretation of the degree of reaction which is significant enough to contraindicate the use of a plasma transfusion is difficult. Reactions of an allergic type are seldom of such consequence as to outweigh the advantages of plasma transfusion in the treatment of shock, burns and hypoproteinemias. It plasma is really as life saving as has been demonstrated under war conditions, withholding it from 20 per cent (to take Levine and State's figures) of patients may be a serious step, not to be recommended in the light of our imperfect proof of the necessity for this privation.

Georgia June Report

The Georgia State Board of Medical Examiners reports the written examination for medical licensure held at Augusta, June 16-17, 1942. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Ninety-four candidates were examined, all of whom passed. Ten physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
George Washington University School of Medicine	(1942)		1
Howard University College of Medicine	(1942)		1
Emory University School of Medicine	(1942)	42	
University of Georgia School of Medicine	(1942)	42	
University of Chicago The School of Medicine	(1941)		1

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Failure to Perform Operation to Reduce Fracture—The plaintiff broke his leg and engaged the defendant physician to treat him. The physician's effort to reduce the fracture was without success. In a subsequent suit for malpractice against the defendant, the plaintiff alleged that the physician negligently, carelessly and unskillfully employed the wrong method of treatment for a period of eight weeks in that instead of operating he merely attached weights to the leg which failed to bring about a proper reduction of the fracture. The defendant contended that he had many times during the treatment advised the plaintiff that an operation on the leg was necessary in order to obtain a good result that the plaintiff consistently refused to permit the defendant to operate and that if there was a bad result that refusal was the direct cause of it. The evidence showed that, after remaining under the defendant's care for several months the plaintiff subsequently went to St. Louis where an operation was in fact performed on his leg with good results. The plaintiff's evidence, in part consisted of the defendant's deposition in which the defendant admitted that he had told the plaintiff that a satisfactory result could not be obtained by using the traction method alone. At the close of the plaintiff's case the trial court directed a verdict for the defendant, and the plaintiff appealed to the Supreme Court of Missouri, division No. 2.

The sole question before the court was whether or not the plaintiff had made out a case which should have been submitted to the jury. In the opinion of the court he had. The defendant's answer and his deposition constituted an admission that he had used a method of treating the plaintiff's leg which he knew at the time was not proper and would not bring about a satisfactory result. The plaintiff as well as his father denied any refusal to submit to an operation as claimed by the defendant and denied that the defendant at any time suggested an operation as alleged in his answer and deposition. Whether or not the plaintiff refused to submit to an operation and whether the defendant advised such an operation were said the court questions for a jury to decide.

The defendant urged that since the plaintiff introduced the defendant's deposition in evidence he was bound by the testimony contained in it and that therefore his case must fail. With this contention the court could not agree. The deposition contained damaging admissions and the plaintiff had a right to introduce it for the purpose of aiding his case. If the evidence of the defendant contained in the deposition as to his advice to the plaintiff to submit to an operation and as to the plaintiff's refusal had been the only evidence on that point, the plaintiff would have been bound by it. But the plaintiff himself denied that he refused or that the physician advised the operation. While a party, said the court, may not directly impeach his own witness it does not follow that he cannot introduce other evidence if of independent probative force, even though it is contradictory of what the witness said.

The defendant argued that the plaintiff introduced no expert evidence to prove that the defendant had been negligent in using a skeletal traction method in lieu of an operation and that he had the right, under the circumstances, to use his own best judgment as to the method of treatment. The defendant's own evidence the court pointed out, was that he used a method which he knew was not practical under the circumstances and would not accomplish a satisfactory result. A dozen expert witnesses could not have added much to that. Expert evidence is not always essential in malpractice cases to make an issue for a jury.

The judgment in favor of the defendant was therefore reversed and the cause remanded for trial.—*Richeson v Roebber* 159 S W (2d) 658 (Mo 1941)

Hospitals Exclusion of Practitioners—The plaintiff had been engaged in the practice of medicine for many years and had, apparently, been utilizing the facilities of the defendant hospital. In 1939 he was notified by the superintendent of the hospital that in order for the hospital to remain on the accredited list of the American College of Surgeons it would be necessary for him to obtain the indorsement of the proper board of officers of that organization. The underlying reason for this notification according to the record, was that the plaintiff, who was described as a general practitioner, had performed certain operations which under the rules could be performed only by specialists and that a continuation of this practice would result in removal of the hospital from the accredited list. The plaintiff filed suit to restrain the defendant hospital from interfering with his practice and obtained a temporary restraining order. Subsequently the trial court dissolved the temporary injunction and denied a permanent one and the plaintiff appealed to the Court of Appeals of Kentucky.

One issue raised in this case was whether the defendant hospital was a public or a quasipublic institution. The court held that it was neither, citing, with approval the case of *Van Campen v Olan General Hospital* 210 App Div 204 205 N Y S 554, where it was said:

There are many public institutions in this state devoted to the care of afflicted and unfortunate people. They may be conducted directly by the state or they might be made by statute corporate bodies. Corporations organized by permission of the Legislature undertake to perform similar duties. The care private corporations. That they are engaged in charitable work for the benefit of the public and thereby affected with a public interest does not make them public corporations. The fact that they may receive a donation from the government to enable them to carry on their work or funds from a city or county to care for sick disabled indigent persons does not affect their character as private institutions.

The second issue before the court was whether or not the plaintiff had a vested right to use the operating room of the hospital in his private practice. Quoting from an annotation in 60 A L R 657 the court said: "Although there are comparatively few cases on the subject under annotation it seems to be the practically unanimous opinion that private hospitals have the right to exclude licensed physicians from the use of the hospital such exclusion resting within the sound discretion of the managing authorities." The high standing of the physician, the court pointed out, was not at all questioned in this case. He had, the record showed, been successful. The court said however, that it had only one question before it—the vested right of the plaintiff to operate in the rooms of the defendant hospital when the hospital for no manifested arbitrary or capricious reason but in the exercise of a reasonable discretion to maintain its institution on an accredited basis, decided otherwise. In the opinion of the court, the plaintiff failed to demonstrate that he had such a vested right, either by contract inherently or as vouchsafed by any constitutional provision. Accordingly the judgment of the lower court dissolving the temporary restraining order and denying a permanent injunction was affirmed.—*Hughes v Good Samaritan Hospital* 178 S W (2d) 159 (Ky, 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Hemoglobin Production Factors in Human Liver—Whipple and Robschtein-Robbins analyzed the stores of hemoglobin producing materials in animal and human livers believing that this knowledge would make for better therapy in man. Normal human liver tissue as compared with that of the normal control animal contains more hemoglobin production factors—a biologic assay ratio of 120 to 160 per cent. Acute and chronic infections do not modify these values. In pernicious and aplastic anemia there are large liver stores of hemoglobin producing factors—a biologic assay ratio of 200 to 240 per cent. Therapy in pernicious anemia reduces these stores as new erythrocytes are formed. Secondary anemia presents a low normal or subnormal liver store of hemoglobin producing factors—an assay of 60 to 130 per cent. Hemochromatosis, erythroblastic anemia and hemolytic icterus in spite of large iron deposits in the liver usually show a near normal biologic assay. Polycythemia shows low reserve stores of hemoglobin producing factors and leukemias a wide range. Hypoproteinemia almost always is associated with low reserve stores—biologic assays of 60 to 80 per cent. In pregnancy, eclampsia and lactation there may be subnormal liver stores of hemoglobin producing factors. Exhaustion of protein stores lowers the barrier to infection and renders the liver susceptible to many toxic substances. Hypoproteinemia under these conditions should be corrected and the patient relieved of a real hazard.

Hyperparathyroidism—Cope reports the 57 cases of proved hyperparathyroidism seen at the Massachusetts General Hospital to emphasize the productivity of painstaking diagnosis and planned surgery. Hyperparathyroidism is primarily a disease of disordered metabolism of calcium and phosphorus and is not a bone disease. Bone changes are secondary to the disordered

metabolism. Recognition of this fact has resulted in the unprecedented number of proved cases. Bones are not involved in mild cases or in cases of severe disease in which the intake of calcium has been adequate. Until the profession realizes this secondary relation of the bone disease, most cases will remain undiagnosed. Any person presenting calcification in the urinary tract or a history of having passed a stone should be suspected of having the disease. Between 10 and 15 per cent of such persons were proved to have hyperparathyroidism. In the last two years the disease was proved in 4 such persons in whom previously the diagnosis had been excluded on the basis of insufficient data. The fasting blood levels of calcium and phosphorus must be checked by experienced laboratory technicians. To evaluate the calcium level the serum protein must be measured; the total blood calcium is composed of bound protein and ionized calcium. Only the latter is elevated in hyperparathyroidism. A persistent low phosphorus level is diagnostic even in the absence of an elevated serum calcium level provided the urinary excretion of calcium is increased. In women there may be a cyclic variation in the excretion of calcium through the kidneys. Of the three forms of treatment suggested (medical, radiation and surgical) only the surgical is effective. Surgery must be precise to meet the challenge of the diagnostician. The problem involves the site and the size of the tumor. The parathyroids lie not only in the neck around the thyroid but also in the mediastinum. The parathyroids adenomatous hyperplastic and uninvolved glands of the 67 patients, were found all the way from the larynx to the heart. This widespread distribution is due to the embryology of the glands. The surgeon must recognize five types of glands: the normal, the adenomatous, the hyperplastic, the secondarily hyperplastic due to a primary renal disease or vitamin D deficiency and the uninvolved glands. When a hyperplastic gland is discovered, all four parathyroids must be found and a subtotal parathyroidectomy done. Total removal of three and subtotal resection of the fourth usually is indicated. When an adenoma is discovered, the surgeon must decide whether further search should be made, 5 of the author's patients had two adenomas. The decision is made on the basis of the size of the adenoma and the degree to which the blood calcium level is elevated. The higher the calcium the greater the weight of parathyroid tissue to be found. An uninvolved gland should never be resected.

Kidney Disease. R. Fitz. Boston —p. 262

Ascorbic Acid Deficiency and Gastric Lesions—Lund shows that patients with gastric lesions commonly have ascorbic acid deficiency not because of any direct metabolic effect of the disease but purely because of deficient dietary intake of the vitamin. He made an attempt to estimate tissue reserves of the vitamin. These reserves are what is probably important in the healing of the wound rather than the output in the urine or the amount in the blood plasma, both of which may be affected by changes much more rapidly than the reserves are. It was hoped that by focusing attention on the reserve a better understanding of the problem might be secured. The author discusses the taking of a dietary history and the determination of vitamin C in the blood plasma and in the white blood cells. The estimate of ascorbic acid reserves is made on the basis of all the data available in each case. In all cases except case 1 there was evidence of at least two of the following kinds: history, simple plasma determination, simple white cell determination and determination of plasma or white cells after test doses. When diet or simple plasma or white cell determinations were the only data available the reserve was taken at the level suggested by the one that indicated the position nearest to its normal. If determinations were made after test doses or treatments, the results of these tests were made the basis of the estimate as follows: if the plasma value was found to be 1 mg. per hundred cubic centimeters the morning after a dose of

1 Gm of ascorbic acid, the value was entered as 75 per cent because, no matter what the original plasma determination showed, the reserve could not have been appreciably lower than this, on the other hand, if the plasma determination was still 0 mg after three daily doses of 1 Gm the reserve was entered as 0. Other results were entered at intermediate levels depending on the best estimate of the reserve. Tables indicate data obtained. Few of 45 patients who underwent operations for gastric lesions had a normal ascorbic acid intake, plasma level, white cell level or reserve. A few patients had such low reserves that they must have been close to scurvy. The greatest number of patients had from 20 to 50 per cent of normal reserves. When nonradical operations were performed, more complications and deaths occurred among patients with low reserves than among those with high reserves. No more complications or deaths occurred among patients with low ascorbic acid reserves after radical gastric operations. It is suggested that more and better vitamin treatment is indicated in cases coming to gastric surgery.

227 277 324 (Aug 20) 1942

*Surgical Treatment of Severe Orchitis in Mumps C Wesselhoeft and S N Vose Boston—p 277

*Eclampsia K W Sewall Boston—p 281
Diabetes Insipidus and Pregnancy Report of Two Cases H Blotner and P Kunkel Boston—p 287
Military Dermatology C G Lane Boston—p 293

Surgical Treatment of Severe Orchitis in Mumps—Wesselhoeft and Vose maintain that although mumps is manifested by a parotitis in the vast majority of cases, the parotids may show no swelling and the submaxillary and sublingual glands may take the brunt of the attack. Involvement of the salivary glands may follow other manifestations of the disease. Thus an orchitis, a pancreatitis or an encephalitis may precede accompany or follow the parotitis. The only manifestations of mumps may be in one of these organs remote from the salivary glands. Here the diagnosis is based on the circumstantial evidence of exposure, the incubation period of approximately eighteen days and the course pursued. Orchitis rarely occurs before the age of puberty. At and above that age its incidence in mumps is 18 per cent. The virus of mumps may invade the seminiferous tubules of the testis, the epididymis and the vas deferens in varying degrees of severity, either simultaneously or separately. Moreover, in rare cases the prostate and the seminal vesicles may also be involved. At the onset of orchitis the scrotal wall is thin, so that one can easily palpate the testis and any enlargement of the epididymis. If the testis does not yield to pressure, presents a stonelike hardness and is very tender it is wise to operate without further delay. The rationale of incising the tunica albuginea in severe orchitis is comparable to that of paracentesis of a bulging, painful drumhead in otitis media. The operation must be done early enough to avoid pressure necrosis in the testis. It is useless to operate when the process is already on the wane. Early operation relieves pain, reduces the fever and avoids atrophy. It is not indicated in mild cases or in those in which an epididymitis predominates. An enlarged, hard, tender testis, with chills and fever, constitutes the indication for surgical intervention. Nitrous oxide and oxygen is the anesthetic of choice. The end results of 10 cases are presented. Moderate atrophy took place in the case in which operation was done too late. In the others there was immediate relief, and no atrophy was apparent at follow-up examination. Fourteen cases of mild orchitis were observed during this period. The patients were not operated on. A follow-up examination on 10 of these revealed no atrophy. The expected incidence of atrophy after mumps orchitis without surgical intervention is 54.7 per cent. The authors' experience suggests that atrophy occurs only after severe cases and that an early operation prevents atrophy.

Eclampsia—Recent theories on the etiology of eclampsia indicate that whatever the cause, eclampsia affects first, or even arises from, the placenta. The chief pathologic damage is to the vascular system. It may have an endocrine origin. Sewall discusses the physiologic and cellular pathology of eclampsia and stresses the damage caused to the vascular system. At the Massachusetts Memorial Hospitals from Jan 1, 1923 to Nov 1, 1941 there were 55 cases of eclampsia among

22,089 hospital and district deliveries, an incidence of 0.249 per cent, or 1 in 402. There were 12 maternal deaths, a mortality of 22 per cent. Among the fatal cases there were 2 vaginal sections, 1 classic cesarean section, 1 manual dilation and 1 high forceps delivery of a large baby through a generally contracted pelvis—this last patient, an emergency case, entered the hospital fully dilated and had several convulsions before and after delivery. Four patients died undelivered, 1 died of general peritonitis after a spontaneous delivery following artificial rupture of membranes to induce labor, and 2 died after normal deliveries following conservative treatment. From 1923 through 1931, when operative deliveries were prevalent, there were 32 cases of eclampsia and 9 deaths, a mortality of 28 per cent. Since then the treatment has been conservative and there have been 23 cases of eclampsia and 3 deaths, a mortality of 13 per cent. Veratrum viride was used at the Massachusetts hospital in 1912 and 1913. It was discontinued because it did not seem to give improved results. However, in those years obstetric treatment was radical, including accouchement force, and little or no treatment for shock, moreover, without intravenous magnesium sulfate therapy it is difficult to see how any medical treatment could have had a fair trial. Workers at the Cincinnati Hospital using veratrum viride, intravenous magnesium sulfate, concentrated dextrose solutions, sedatives only for extreme restlessness and labor and, rarely, morphine have treated 120 consecutive cases of eclampsia with 2 deaths, a mortality of less than 2 per cent, which is remarkable. Veratrum viride should be used with great caution. Until results are obtained from others who are now using the drug according to the routine of Bryant and Flemming, it should not be routinely employed.

Report on Results of Electric Shock Treatment on Mental and Emotional Symptoms T Kennedy and B Wiesel New York—p 1663

Common Masquerading Lung Disease—Primary carcinoma of the lung involving one part of a branching bronchial system may masquerade under various guises. The presenting symptoms and one that caused the patient to seek help among 153 encountered by Overholt within the last ten years were cough in 124, chest pain in 65, chills and fever in 60, hemoptysis in 55, dyspnea in 52, loss of weight in 51, weakness in 41, wheezing in 10, gastrointestinal upsets in 9 and arthritis in 4. The original diagnosis in 95 was tuberculosis, unresolved pneumonia, pulmonary abscess, bronchitis, asthma, heart disease, pleurisy or a malignant neoplasm. In most instances the primary pathologic process failed to produce its shadow in the roentgenogram or on the fluoroscopic screen. The changes observed were secondary effects and these were of a highly variable nature. The great roentgen variation is due to the fact that the disease is one involving one part of a branching bronchial system. The disease masqueraded for almost a year before the true diagnosis was established. The method of establishing the diagnosis in the 153 cases was by bronchoscopy in 63 per cent, surgical exploration in 24 per cent, biopsy in 6 per cent, aspiration in 2 per cent and necropsy in 5 per cent. It is significant that this internal cancer is strategically located and is within the range of bronchoscopic vision and accessible for biopsy in most cases, which method may be used even in the earliest stages of the disease and before the lesion is large enough to produce bronchial occlusion with telltale atelectatic signs on the roentgenogram. Of the 153 patients surgical intervention was offered to only 75, 37 were in a hopeless condition, 8 had palliative resection and 30 had curative resection. Eighteen of the 30 are living, 4 having survived for more than five years and

14 for less than five years. Cancer of the lung is now one of the most challenging and important diseases of the chest in patients 40 to 65 years of age, particularly men. Many patients ask for help at a time when the lesion is still confined to the lung. It need not be a menacing disease. It is too common to be forgotten. Early discovery in many cases will be rewarded by a reasonably good chance of cure.

Roentgen Treatment of Cancer of Cervix—Of 557 patients with group 1, 2 and 3 cancer of the cervix treated from 1931 to 1935, 72, 48 and 38 per cent respectively survived for five years with all types of treatment. When Reinhard and his associates correlate the five year survival of 457 of the patients on the basis of treatment, they find that of 227 receiving primary irradiation (one or two small doses of 200 kilovolt x-rays, having a half value layer of 0.9 mm. of copper delivered anteriorly and posteriorly through 20 by 20 cm. ports at a skin target distance of 80 cm., insertion of radium tubes of 100 to 200 mg. radium content with 1 mm. of platinum and 1 mm. of steel filtration in the uterine canal and gold radon seeds with 0.3 mm. of gold filtration in the cervix and palpable part of the tumor) and of 230 who received supplementary (protracted irradiation either from radium packs or 200 kilovolt x-rays radium tubes and seeds or any combination of these) in addition to the primary irradiation, the survival percentages for the three clinical groups of cancer were respectively 97, 66 and 57 for the 227 and 66, 40 and 31 for the 230 patients. The definite difference in the survival rate following the two types of treatment may be due to several individual or a combination of factors: extent of the disease, biologic variation in the disease and the patient, age of the patient and supra-lethal influence of additional radiation. A study of these factors failed to show that any of them but age had any influence. A better survival was associated with the older age groups. Isodose and dosage distribution curves show a steep gradient, from 2 to 5 cm. lateral to the midline, which is reflected in the progressively poorer survival with increased spread of the disease. Doses at the 2 cm. mark within a range of 4,000 to 8,000 roentgens of primary radiation only, produced a 75 per cent five year survival free from disease of patients with group 1 and 2 cancers and a 55 per cent survival free from disease of the group 3 patients. Because of the poorer survival of group 3 patients in whom the disease has presumably spread to regions receiving lower doses, it would seem reasonable to conclude that the dose to the lateral portions of the pelvis should have been increased. Of those patients with all three groups of cancer receiving supplemental irradiation the highest survival followed doses of less than 2,000 roentgens in addition to the primary irradiation.

Blood Findings in Cyclotron Workers—Warren determined the blood counts and hemoglobin levels for three to thirty months of 85 persons exposed to slight radiation from cyclotrons and temporarily radioactive isotopes. Most persons under

these conditions had no significant changes that were not explained by intercurrent disease. In 4 there were minor variations in the leukocyte count. As with exposure to roentgen or radium radiation a transient depression in the leukocyte count was followed by an elevation. This change occurred more rapidly in lymphocytes than in granulocytes. Persons with an unstable bone marrow when subjected to only minor exposure to radiation should not work where they are exposed to radiation.

Multiple Primary Tumors—Among 3,700 consecutive necropsies 42 examples of multiple independently developing primary tumors were recorded. An analysis by Schmidt shows that in 38 there were two tumors and in 4 three tumors. A combination of two benign tumors was seen only twice, a combination of a benign and a malignant tumor twenty-seven times, two benign tumors and one malignant tumor three times, two independent malignant tumors nine times and two primary malignant tumors and a benign tumor once. The ratio of a benign malignant to a malignant malignant combination is about 3 to 1 as compared to 6 to 1 reported by Egli in 1914 and 25 to 1 by Puhf in 1927. The explanation for the higher ratio probably lies in the inclusion of brain tumors previously less frequently diagnosed. Of the 42 cases 24 were observed roentgenologically. The relative rarity of multiple primary malignant tumors may be due to the fact that in most of these subjects the remaining span of life for the development of additional neoplasms is definitely limited, to diagnostic limitations in the living patient and at necropsy and to the fact that tumor resistance or tumor immunity may be produced by the first tumor. It seems probable that elements of immunity and tumor resistance play a part in man as they do in animals. Spontaneous cures of undoubted malignant neoplasms have been reported occasionally and so has the unpredictably different course in certain apparently analogous cases. Acquired immunity may at some future time play an important part in the war against tumor and malignant growth.

Sulfonamide Derivatives and Zinc Peroxide in Gas Gangrene—Caldwell and Cox determined the relative prophylactic and preventive value of certain sulfonamide derivatives and zinc peroxide paste in combating gas gangrene in experiments in guinea pigs infected with *Clostridium welchii*. After observing the effect of inoculation with a vegetative strain of the organism in more than 500 guinea pigs they decided that no animal died from gas gangrene unless the infection extended into the abdominal wall causing considerable necrosis and lysis of the musculature of the extremity. Many animals could completely arrest local edema, serous exudate and crepitation. In comparing the data of their experiments they find that when sulfanilamide was injected intraperitoneally it only slightly

retarded the progress of gas gangrene as compared to surgical debridement alone. It was of no prophylactic value as it did not of itself prevent gas gangrene in a single instance. When the average death time and the number of survivals in comparable groups with closed wounds, open wounds and debrided wounds is analyzed it is seen that sulfanilamide administered systemically only slightly prolonged the survival period. Experimental gas gangrene is much more rapidly progressive than that encountered clinically in compound fractures. When a group in which zinc peroxide paste was applied to the wound is compared with a group in which sulfanilamide was implanted one hour following inoculation and the wounds allowed to remain closed neither sulfanilamide nor the zinc peroxide prevented gas gangrene in most of the animals. Zinc peroxide did definitely prolong the average death time beyond that of the control group. As a local dressing it is valuable but as a prophylactic agent it is not as effective as other measures. Both drugs acted merely as inhibiting factors. Experiments performed to determine the relative effectiveness of sulfanilamide, sulfathiazole and sulfadiazine when implanted at the same time as the infecting organisms indicate that sulfathiazole is probably the most effective in preventing the development of gas gangrene. Although the infection was of the most fulminating type, the immediate use of any of the sulfonamides in the wound prevented its progress in most instances and was responsible for a number of survivals. In the control group of 85 animals the survival rate was 11.8 per cent as compared to 73.3 per cent of 60 animals in which sulfonamides were placed in the wounds and the wounds closed primarily. The significance of this is increased when it is considered that if sulfanilamide was implanted one hour after inoculation most of the animals died as a result of gas gangrene. When a sulfonamide was implanted six hours after inoculation and the wound debrided, the drug reimplanted and the wound closed 49 of 59 animals survived. Sulfathiazole was a most valuable adjunct to other measures. Only clinical trial in a large number of cases will substantiate the experimental observations but on the basis of experimental evidence the local implantation of sulfathiazole at the scene of the accident is encouraged.

Diethylstilbestrol in Abortion and Premature Labor—Karnaky used the new synthetic diethylstilbestrol for the treatment of premature labor and of threatened and habitual abortion. For threatened and habitual abortion when severe labor pain and some vaginal bleeding were present he gave 25 mg. of the drug into the anterior wall of the cervix and five 5 mg. tablets every fifteen minutes as long as there was any uterine pain. If the pain returned and was severe the five 5 mg. tablets were taken every fifteen minutes until it was entirely gone. After the pain ceased, 10 mg. of diethylstilbestrol in tablet form was taken every hour for six doses, then 5 mg. every hour for six doses and then 10 mg. every night until the eighth month. The injections may be omitted and only the tablets used if the patient is seen early and pain and bleeding are mild. Too little but not too much diethylstilbestrol can be given. In habitual abortion cases 10 mg. of the drug was given once or twice a day as soon as pregnancy was diagnosed. The uterine pain of threatened, habitual, complete and incomplete abortion and normal labor can be stopped immediately by giving 25 to 100 or 200 mg. of diethylstilbestrol in oil into the anterior wall of the cervix. The hard contracting uterus of abortion can be made to soften and assume its normal consistency within thirty to sixty seconds and remain so for six to eight or to twenty-four hours or longer. Diethylstilbestrol may replace corpus luteum altogether for the treatment of threatened and habitual abortion and premature labor. No deaths in utero have been observed after 25 to 6,000 mg. of it in twenty normal pregnancies so diethylstilbestrol in therapeutic doses apparently will cause no harm. Formerly apparently sterile patients who become pregnant after study should be given 10 mg. of diethylstilbestrol by mouth every night for at least seven months. If uterine pain or bleeding starts at any time five 5 mg. tablets should be taken immediately and repeated every fifteen minutes until the pain and/or bleeding are stopped, followed by 10 mg. every hour for six doses, 5 mg. every hour for six doses and then 10 mg. every night through the eighth month.

Corpus Luteum Extracts in Obstetrics—Falls and his co-workers used corpus luteum extracts in 650 obstetric cases to inhibit uterine contractions and to prevent threatened and habitual abortion. The intramuscular or intravenous injection of the material will not prevent abortion when the fetus is dead. Injections are contraindicated when a uterine infection or a mole pregnancy exists. Corpus luteum extracts have proved efficacious when a surgical emergency necessitated laparotomy in preventing the onset of labor and abortion. Patients with fibrotic uteri and previously sterile patients who have eventually become pregnant should be given injections of the extract prophylactically until the fetus has reached viability. No untoward results followed the injection of aqueous preparations even when given in 15 cc doses intravenously. Successful treatment depends on the regular administration of adequate dosage and on the continued cooperation of the closely supervised patient.

Intravenous Amino Acids for Nutrition—Landesman and Weinstein describe their experience with the parenteral use of an enzymatic hydrolyzed amino acid preparation for 75 patients who could not ingest digest or absorb food normally. The enzymatic hydrolysate of casein, amigen, is supplied as a refined powder ready for use. The amigen is weighed out in 100 Gm portions and each portion is dissolved in 1 liter (1,000 cc) of distilled water, passed through a Berkefeld filter W, diluted to a 5 per cent solution under sterile precautions, sealed in a sterile container, steamed over a water bath for thirty minutes and then stored on ice or at room temperature. It appears that 0.7 to 0.8 Gm of amigen per kilogram of body weight daily will maintain an active man in positive nitrogen balance. It has been the authors practice to supply daily 50 to 100 Gm of amigen in 2.5 or 5 per cent solution to which is added sodium chloride vitamins and dextrose in sufficient amounts to bring the caloric intake to 1,200 to 2,000 calories. The dosage is limited by fluid tolerance and certain toxic reactions. Urticaria angioneurotic edema or a foreign protein febrile response were not observed. A group of patients given 1,000 cc of a 5 per cent amigen solution in one and a half hours frequently experienced flushing of the face, a feeling of warmth and frontal headache. A few had retching and vomiting but none of these symptoms occurred when amigen was given slowly, 120 to 240 cc per hour. The one reaction that has caused concern was phlebitis following the administration of hypertonic solutions, a 2.5 per cent solution is approximately

isotonic and is scarcely more irritating than isotonic sodium chloride solution. A 5 per cent amigen solution may be given continuously for forty eight hours without causing phlebitis. The swelling that occurs disappears completely without inflammatory reaction within twenty four hours. If 5 to 10 per cent dextrose is added so that the solution becomes decidedly hypertonic, endophlebitis may occur. This danger may be minimized by inserting the needle at the junction of two veins and administering 2 to 4 cc of the solution per minute. The two facts that strongly support the theory that this amino acid mixture is utilized by the body for nutrition are that the amino acids are rapidly absorbed from the blood stream by the body tissues and are not lost in the urine and that a positive nitrogen balance may be maintained with amigen as the sole source of nitrogen. The prime indication for the administration of amino acid is a starvation state. This therapy is not an adequate substitute for plasma infusions in hypoproteinemia but it should be used as a supplement to plasma.

Amyloid Gitter—The deposit of amyloid in the thyroid is most infrequent. Walker reports 2 cases of extensive amyloid infiltration of the thyroid. A search of the literature discloses 56 cases, bringing the total to 58. In the first case the amyloid infiltration was associated with lipomatosis as well. As the thyroid is an organ in which fat tissue is rare, this finding would suggest that there may be some more than casual relationship between the two conditions. This is supported by several other examples in the literature. In no case of thyroid amyloidosis reported has there been any evidence of insufficiency. The most common diagnostic error is to conclude that a malignant growth is present when actually amyloid is responsible for enlargement, increased consistency and nodularity of the thyroid. On the other hand, amyloid may cause considerable enlargement of the thyroid without any change in consistency.

Heredity as Etiologic Factor in Cancer—Macklin shows that the foundation for the belief that chronic irritation is a cause of cancer is not as sound as some believe it to be. With the discovery that mammary and uterine cancer could be produced experimentally in animals by estrogen the emphasis has shifted from a vague conception of chronic irritation to estrogenic influence. This theory may be true, but estrogens are supplied by the organism itself, and their production is under the influence of heredity. All women with normal ovaries produce estrogens, but mammary or uterine cancer does not develop in all women. Therefore there must be some difference between those who do and those who do not have cancer. There are at least five possible ways in which they might differ: in the quantity of sex hormones generated, in the quality of sex hormones produced, hereditary differences in the tissue response to a uniform stimulus of sex hormone, hereditary differences in the inhibiting factors for tumor growth in different women and differences between the internal environment of those in whom cancer develops and of those in whom it does not. If the latter is true, that the differences are hereditary in nature, women of the same stock should be and are more alike than unrelated women, and cancer is found more often in related than in unrelated women. Heredity is of importance in that it may become the implement for the achievement of early diagnosis.

Diphtheria Immunization of Adults—Leete reports results of nine years of immunizing the Schick positive staff at the Hull City Hospital. The 388 persons in the group were more than 16; most of them were the nurses and domestic staff between 18 and 20 years of age. Three injections of toxoid-antitoxin floccules were given at monthly intervals up to 1935 and Schick retesting was done four weeks after the last dose. From March 1935 0.3 cc of alum precipitated toxoid followed after four weeks or a little longer by 0.3 cc with a Schick retest one month later, was the procedure. There were no severe reactions. The results with toxoid-antitoxin floccules as a whole were poor; the Schick conversion rate was 78 per cent as compared with 100 per cent with alum precipitated toxoid. Subjects likely to have severe reactions are those with pseudonegative reactions to the Schick test; they should not be immunized. It is probable that all pseudoreactors are Schick negative. The author has never seen in an adult an undoubted combined or pseudopositive reaction. In a series of 51 pseudoreactors 48 were definite pseudonegatives and in 3 it was possible that the reading was a combined one.

Terminal Ileostomy in Ulcerative Colitis—Indications for terminal ileostomy are difficult to define according to Mangot, because ulcerative colitis is protean in its manifestations and because of the way it responds to various types of treatment. It is indicated when efficient medical treatment has failed to bring about a cure or to relieve symptoms when certain complications such as subacute perforation or abscess, fistula, sinusitis, obstruction massive hemorrhage or polyposis occur or when the possibility of a malignant condition cannot be excluded. In the first group are included all those patients who were intractable to continuous medical treatment conducted under the best controlled conditions in a hospital for about six months and those chronic ambulatory patients who have been totally incapacitated for three months or more each year. Terminal ileostomy preferably with implantation of the proximal and distal ileal limbs into separate incisions in the abdominal wall, has replaced appendicectomy, cecostomy and the ileo case of idiopathic ulcerative colitis successfully treated by terminal ileostomy followed a year later by restoration of intestinal continuity is described. The problem is to decide whether the colitis is healed after terminal ileostomy and, if it is, whether closure of the stomas and restoration of the continuity of the intestinal canal is safe.

Indications for Intrauterine Interventions—Schumacher outlines the principles followed at the Luzerne clinic in the treatment of abortions. Even in incomplete afebrile abortion the patient is observed for twenty-four to forty-eight hours. The general condition is determined, a gynecologic examination is performed, the sedimentation speed, leukocyte count and differential blood picture are made and the urine is examined for albumin, sugar and morphologic elements. Eccholics are given and in cases of severe hemorrhage a blood transfusion. If after an observation period of one or two days there is no fever, the cervix is dilated, the uterus is curetted, the uterine cavity is swabbed with iodine, and a strip impregnated with iodochloroxyquinoline is inserted into the cervical canal for twenty-four hours. Intrauterine intervention is withheld in febrile abortion. All examinations, except the gynecologic, are carried out as in afebrile abortion. The gynecologic examination is postponed in order not to disseminate the infection. If a previous intrauterine intervention is suspected, local examination is done at once in order to ascertain a perforating injury. Eccholics and sulfanilamide are given. This medication often effects a spontaneous evacuation, so that after three or four afebrile days the curettage can be restricted to mild scraping with a dull curet. This intervention must be preceded by a gynecologic examination to rule out parametrial inflammatory processes. Gynecologic examination must be made before defervescence whenever there are peritoneal signs or when a suppurating process is suspected. Sulfathiazole has recently replaced other sulfonamide derivatives in the treatment of febrile abortion. If previous intrauterine intervention is admitted or there is justified suspicion of a criminal abortion the patient, even if afebrile, is observed for at least five to eight days. If no fever develops, curettage is done. In cases of metrorrhagia the indications for curettage, as regards time and the existence of fever, are the same as in abortion.

Functional Test of Adrenals—Saurer directs attention to the adrenal functional test described by Cutler, Power and Wilder in 1938 and reports her own experiences with it on 50 persons, including healthy subjects, patients with various disorders and 3 patients with Addison's disease. Healthy subjects and many patients exhibited in the four hour urine of the third day a nearly constant level of from 70 to 160 mg. of sodium chloride per hundred cubic centimeters or from 42 to 96 mg. of chloride. The four hour urines of the third day of the 3 patients with Addison's disease showed sodium chloride concentrations of 456, 262 and 737 mg. per hundred cubic centimeters and chloride concentrations of 274, 157 and 442 mg. per hundred cubic centimeters. The more thorough investigation of the mode of development of the increased concentration disclosed factors which throw some light on adrenal insufficiency and are important for the differential diagnosis. Observations by Cutler and his associates indicate that adrenal insufficiency manifests itself in an increased sodium chloride concentration in the four hour urine of the third day of the test period. The author detected deviations from the normal

sodium chloride concentrations in the same or in the opposite direction from that in Addison's disease, also in other cases, particularly in disorders accompanied by water retention. Interesting deviations from the normal were detected particularly in certain types of emaciation and in disorders of the joints, particularly in polyarthritis. Closer investigation of the regulatory disturbances in the water-salt economy of these cases might prove instructive. In order to utilize the results or a test for the diagnosis of adrenal insufficiency the other clinical symptoms must also be taken into consideration. Adequately compensated cases of Addison's disease may show normal values in Cutler's test. It is possible that in these and in doubtful cases the prolongation of Cutler's tolerance test over a longer period might reveal changes indicative of adrenal insufficiency. The author concludes that Cutler's method is not a specific test for the adrenal function but that with consideration of the quantitative values of the fluid intake and the urinary and sodium chloride eliminations and their correlations it can be utilized as a general functional test of the water-salt exchange.

Annali d'Igiene, Rome**51 673-736 (Nov.) 1941 Partial Index**

- *Effects of Usual Chemical Preservatives on Vitamins in Preserved Food. I. Peragallo—p. 691

Effects of Chemical Preservatives on Vitamins—Peragallo determined the amount of vitamins in food preserved with boric, salicylic and benzoic acids and their esters. The determinations were made shortly after preservation of food and again one month and three months later. He found that the amount of vitamins in food preserved with these acids and their esters did not diminish.

Revista Argentina de Cardiologia, Buenos Aires**9 1-86 (March-April) 1942 Partial Index**

- Electrocardiogram in Simultaneous Enlargement of Heart Ventricles. B. Moia, L. H. Inchausti, R. Chiria Olmedo and F. F. Batlle—p. 1
 *Potassium Thiocyanate in Therapy of Arterial Hypertension. B. Moia and R. Quezada—p. 41

Potassium Thiocyanate in Arterial Hypertension—Moia and Quezada administered potassium thiocyanate to 30 patients with essential hypertension whose blood pressures were over 200 mm. of mercury systolic and 120 diastolic. None of the patients were in the malignant phase or had congestive cardiac failure. After more than four years of the usual treatment they were treated for ten months exclusively with potassium thiocyanate, 0.3 to 0.6 Gm. daily. The blood concentration of the drug was determined weekly by the micro-method of Griffith and Lindauer. Results were good in 6 (20 per cent) with a decrease in blood pressure of 70 to 80 systolic and 20 to 25 diastolic, they were fairly good in 13 (43.3 per cent) with a decrease of 30 to 40 systolic and of 10 to 15 mm. diastolic. Larger doses did not alter the results in this group even when blood concentration higher than 10 mg. of potassium cyanate per hundred cubic centimeters was attained. In the other 19 patients (36.7 per cent) the results were poor. No relation was found between the condition of the electrograms and the results obtained. Patients whose blood pressure was unstable responded better to thiocyanate therapy. The results in these patients were more favorable and more persistent. All the patients of the first group and some of the second group were relieved of subjective symptoms, but not those of the third group. The subjective amelioration obtained by autohemotherapy was more accentuated and more lasting than that obtained with thiocyanate therapy and did not cause any of the disturbances which appear especially during the first days of treatment with thiocyanate. Only 2 patients had symptoms of intolerance, such as mild erythrodermia, which rapidly disappeared on withdrawal of the drug. The authors conclude that the administration of thiocyanate should be persisted in only when results comparable to those of the first group are obtained or, even if no reduction in blood pressure is obtained, when the amelioration of subjective symptoms is greater than that which can be attained by other therapeutic measures.

Book Notices

Textbook of General Surgery By Warren H. Cole, M.D., F.A.C.S., Professor and Head of the Department of Surgery, University of Illinois College of Medicine, Chicago, and Robert J. Mann, M.D., Associate Professor of Clinical Surgery, Washington University School of Medicine, St. Louis. Third edition. Cloth. Price \$8.15. 1067 with 538 illustrations. New York & London: D. Appleton Century Company Incorporated, 1941.

This book was first published in 1936, revised in 1939 and revised again in 1941. The many advances in surgery have required such extensive revision of the text that it was necessary to reset the type completely for this volume. This is a textbook of surgery designed primarily for the medical student. The material is presented clearly and simply and from the physiologic point of view, although pathogenesis and surgical pathology are given due consideration. Omission of detailed considerations of operations yield brevity and avoid confusion in the mind of the student. Those features of the specialties which are important to the general surgeon are included. There are separate chapters for genitourinary surgery, gynecology and anesthesia, subjects which were slighted in preceding editions. Because of the war, particular attention is given to open wounds and burns, treatment of fractures, and the value of silk in the repair of wounds. Separate chapters are devoted to amputations and to diabetes. The effectiveness of sulfonamide compounds is discussed wherever such treatment is warranted. This book has always been noted for its fine bibliography. In this volume a number of teachers of surgery representing several schools have aided in the revision of the text. Certainly medical students will find this book an asset in the study of surgery.

Biological Symposia. A Series of Volumes Devoted to Current Symposia in the Field of Biology. Edited by Jacques Cattell. Volume VII: *Visual Mechanisms*. Edited by Heinrich Klüver. Professor of Experimental Psychology, The University of Chicago, Chicago. Cloth. Price \$3.25. Pp. 322 with illustrations. Lancaster, Pa.: Jacques Cattell Press, 1942.

The present volume originated in a series of symposiums held at the University of Chicago, in which distinguished scholars from various schools participated. A few contributions not presented at this particular symposium (Sept. 24, 1941) were added, and some of the original contributions have been considerably expanded. The result is a rather remarkable compilation of knowledge and opinion on the subject of vision, considered from the biophysical, chemical, physiologic, anatomic and psychologic points of view.

Approaching the volume from the point of view of the clinical ophthalmologist, the reviewer finds himself adopting the statement attributed by Professor Klüver to Charles Darwin, namely that "he got a kind of satisfaction in reading articles which (according to himself) he could not understand." Certainly he is not in a position to evaluate critically most of the contributions of these scholars in the top flight of pure science. But at least he can be stimulated to think a little more intelligently on certain aspects of vision entirely neglected by the average clinician and yet with a definite bearing on certain of his problems. From such a wealth of material, one can scarcely do more than list the subjects covered, with brief notes on certain points which could seem to be of general interest.

Professor Hecht discusses previous efforts to apply the quantum theory to the process of vision and describes his own measurements. These indicate that, "in order to see, it is necessary for only one quantum of light to be absorbed by each of five to fourteen retinal rods, an observation in harmony with the quantum theory, since one quantum of light and energy reacts with one molecule of visual purple. Krause and Wald both discuss the chemistry of the photosensitive substances found in the retina. The probable processes by which vitamin A is converted to visual purple (rhodopsin) are described. Krause describes a number of other substances which seem to be independent of the main cycle but which probably play a definite part in vision. Wald traces the now generally accepted cycle: Vitamin A + protein → rhodopsin → light → retinene + protein (visual yellow). Wald has studied the process in a number of animals and fishes. Marine fishes possess the typical

rhodopsin system while fresh water fish produce not rhodopsin, but a related substance named by Wald porphyropsin. Strangely enough this is true also of fish such as the salmon, which live in the sea but spawn in fresh water. In these fish the porphyropsin system predominates. In animals such as the chicken, in whose retina cones predominate Wald describes a third photopigment which he calls iodopsin. Gellhorn describes the effects of oxygen deprivation on the visual functions, showing that it results in pronounced reduction of the visual sensations and of voluntary reactions to them while leaving autonomic responses such as the response of the pupil unaffected.

Four papers deal with the results of electroencephalography as applied to the problems of vision. Case made observations on 6 persons whose visual pathway to one occipital lobe had been interrupted by various lesions. The alpha waves in such instances were lost or greatly weakened on the side of the lesion. The paper of Marshall and Talbot, a careful attempt to correlate the electrical with the subjective phenomena of vision leads the reviewer into a rarefied atmosphere not conducive to intelligent comment. Perhaps the most important essay in this group is that of von Bonin and his associates, which records the mapping of association areas in the occipital lobe and their connections with other parts of the brain by means of action current readings after application of strychnine to small areas.

In the anatomic group Polyak offers a short outline from his larger work (recently reviewed) concerning the inner retinal structures and their connections while Walls traces the evolution of the visual cells from lower to the highest organisms. Surprisingly enough his evidence indicates that the cone was the most primitive of the visual cells that the rods developed from it in somewhat higher organisms, the cones being lost entirely and developing secondarily from rods in the higher cone bearing mammals.

In the psychologic group Professor Klüver reports careful observations on a series of monkeys in which both occipital lobes had been resected. By study of reflexes conditioned by visual stimuli he has estimated the amount and character of visual function remaining in such animals. Although certain reactions to light can be observed, Klüver is forced to the conclusion that such reactions depend entirely on the amount of light reaching the eyes and hence the lower centers and that all 'visuospatial properties as determinants of behavior are absent. The concluding paper, by K. S. Lashley, offers an explanation of vision and especially visual memory in terms of a series of 'resonators' in the cerebral cortex.

Morris Human Anatomy. A Complete Systematic Treatise. Edited by J. Parsons Schaeffer, M.D., Ph.D., Professor of Anatomy and Director of the Dankl Baugh Institute of Anatomy, Jefferson Medical College, Philadelphia. Tenth edition. Finkbold. Price \$12. Pp. 1635 with 1155 illustrations. Philadelphia: Blakiston Company, 1942.

Prof. C. M. Jackson, editor of former editions of this book, withdrew on account of illness from the arduous work of editing the tenth edition and was succeeded by Dr. J. Parsons Schaeffer, professor of anatomy at Jefferson Medical College. Professor Jackson however continues to be one of the contributors to the present edition, among those acting in this capacity for the first time and their sections are: Prof. J. C. B. Grant of the University of Toronto on the musculature; Prof. Bradley M. Patten of the University of Michigan on the cardiovascular system; Prof. Harold Cummins of Tulane University on the skin and mammary glands; and Prof. Olof Lurcil of the University of Oregon on the nervous system. Death has removed Professors Bardeen Senior and Stockard from the list of contributors, and Professor Hardesty has retired from active participation. The size of the pages has been increased in both dimensions. Each of the sections has been revised and some of them have been rewritten. The section on developmental anatomy by Prof. Richard E. Scammon of the University of Minnesota is in a very attractive form with numerous illustrations of the developing embryo and charts, curves and formulas illustrating the growth of the body in prenatal and postnatal life. Many of these illustrations are from Professor Scammon's own laboratory. However some embryologic descriptions which were previously included in the section on developmental anatomy in this edition have been prepared by the several contributors and are included at pertinent places in the text of the various

sections. This edition is exceptionally well illustrated and many of the illustrations are in color. The editor has continued the use of the BNA terminology in Anglicized form, with some exceptions. The latest available revision of the BNA (*Basle Nomina Anatomica*) is the *Jena Nomina Anatomica* and is known in the literature as the JNA or the INA. In this edition when these names differ from the BNA they are listed as INA terms and placed within parenthesis after the BNA Latin terms. The editor points out that confusion has been caused by these conflicting terminologies and that to eliminate the confusion an International Congress of Anatomical Nomenclature was established by the International Congress of Anatomists at Milan in 1936. This commission accepted the modified BNA, that is, the NK-INA, usage as the basis for an Official International Revision of anatomical names. Present world conditions, however, have made it impossible to predict when the commission will complete its work and make the new list of names generally available.

Personality and Mental Illness. An Essay in Psychiatric Diagnosis. By John Bowlby, M.D., Psychiatrist, London Child Guidance Clinic, London. Cloth. Price \$2.75. Pp. 250. New York: Macmillan Books, Inc. 1942.

The relationship of what is understood as "personality" to types of mental disorders is an old subject for discussion appearing time and time again throughout the history of psychiatry and still popular in many psychiatric centers. This book is a serious attempt to create a new orientation in the field, and to this end the author, who is psychiatrist at the London Child Guidance Clinic and physician to the London Clinic of Psychoanalysis, has made an approach to the problems of mental disease by evaluating what he understands as basic personality traits rather than the presenting symptoms of emotional distortions. The numerous aspects of this rather complicated field for scientific investigation of the neuroses and psychoses are introduced by discussions of the ideas and classifications proposed by Kraepelin, Bleuler, Adolf Meyer, Kretschmer, Kahn and others. This is followed by a schedule of traits characteristic of the main types of personality, with particular emphasis on the schizoid and syntonic varieties, arranged in a practical way for clinical use. There is presented also a practical clinical method of measuring and describing personality forms. Tabulations of personality traits for 36 psychotic patients and for 29 patients suffering from neurotic symptoms, presented with descriptions of classic unstable personalities, illustrate the method of study. Thirty-three traits are selected as being particularly valuable for diagnostic purposes. One section of the book is devoted to the psychoneuroses. It contains many suggestions for diagnosis and regrouping of the types in a classification scheme that has some clinical advantages. Much of the subject is still in stages of research, as the author himself recognizes. Throughout the text a number of attractive research leads are pointed out, and the urgency of more original work in psychopathology is stressed. Although many of the conclusions are tentative, the ideas offered and the method of study proposed make this work a contribution to the literature on psychiatry, and students of this subject should profit by the information to be found on its pages.

The History of Alpha Kappa Kappa. By Leo Douglas van Antwerp, A.B., M.D., F.A.C.P., Boards. Pp. 224 with illustrations. Menasha, Wis.: George Banta Publishing Company, 1942.

The Alpha Kappa Kappa medical fraternity was founded at Dartmouth College in 1888. Prominent among the founders was Dana Crosby, whose father, grandfather and great grandfather were physicians. In three generations of this family there were nine physicians, all of whom received their medical education at Dartmouth. Although Dartmouth traditions were deeply ingrained in the founders of Alpha Kappa Kappa, they probably never visualized that the fraternity would attain national and international scope, it was their intention to found a society built on lasting principles as an aid in their studies. While the committee—Paul D. Cimm, grand historian, William A. Mann, grand president and Lee D. Van Antwerp, editor of the *Centaur*—which prepared this history could not find some early details of organization of the fraternity, copies of reports

of the early annual conventions were available. A brief history of the founding of each of the sixty-one chapters, together with many group pictures of chapter members, add to the interest of this volume. While the actual designer of the beautiful Alpha Kappa Kappa badge is not known, it is recorded that Dr. E. J. C. Ellis, Alpha '90, was on the committee that designed the badge. This volume contains also the ritual of initiation and several pages of fraternity songs.

Diseases and Injuries of the Larynx. A Textbook for Students and Practitioners. By Chevalier Jackson, M.D., Sc.D., LL.D., Honorary Professor of Broncho Esophology, Temple University, Philadelphia, and Chevalier I. Jackson, A.B., M.D., M.Sc., Professor of Broncho Esophology, Temple University. Second edition. Cloth. Price \$8. 1p. 633 with 209 illustrations. New York: Macmillan Company, 1942.

A book by the Jacksons is an event for laryngologists. While this work, with a slightly altered name, is a second edition, it has additions which increase its value materially.

In this country, most of the information on diseases of the larynx is to be had only in specific chapters which are a part of ear, nose and throat textbooks. There is nothing comparable recently in English to this edition in authority or completeness. It is, furthermore, distinctly a product of the authors and their school.

Different from similar works which not only represent the experience of the author but include to a large extent a more or less critically examined cross section of the opinions of the laryngologic world in general, this textbook is, as said, peculiarly individual. The authors have made laryngologic history, and their impress on it is tremendous. Every chapter shows this plainly: many of the clinical pictures were first described by them. If they were not the original observers they gave many conditions their definitive outlines and invented, it necessary, the proper terms expressive of these conditions. Throughout one is impressed with the clinical acumen, the painstaking observations and the meticulous handling of disease so characteristic of Chevalier Jackson. Only by comparison with what has gone before can the specialty's debt be understood.

There is no need to discuss the various chapters in detail. Those who wish to study the larynx and its diseases will find here a masterful and scholarly exposition.

An Old Doctor of the New School. By James C. Wood, M.D. Cloth. Price \$1.00. 1p. 335 with 41 illustrations. Caldwell, Idaho: Easton Printers, Ltd. 1941.

This is the autobiography of a physician who has had an interesting and successful career, which he developed mostly in the states of Michigan and Ohio. Many others will agree with him that Cleveland is one of the friendliest of our large cities. The details which he remembers of the incidents of a happy childhood on the home farm are amazing. His delineation of the difference in temperaments of a misrattled and incompatible team of horses with which he worked early and late is well done. Dr. Wood has been a staunch member of homeopathic medical circles, having taught in the homeopathic department of the University of Michigan and at the Cleveland Homeopathic Medical College. He has a chapter on the principles of homeopathy, one on homeopathy in gynecology and surgery and among others chapters on medical politics, medical derelicts and Washington, where he visited the White House with President Harding's physician, Brig. Gen. Charles E. Sawyer, also a homeopathic physician. He was for many years a member of the Board of Governors of the American College of Surgeons. He visited clinics in Europe and wrote a textbook on gynecology. In all Dr. Wood has had a full and happy life and now at 84 still fully enjoys the fruits of many years of devotion to his family and his profession.

Big Spring. The Casual Biography of a Prairie Town. By Shlue Phillips. Cloth. Price \$2.00. Pp. 231 with drawings by Jerry Bywaters. New York: Penitence Hall, Inc. 1942.

This "casual biography of a prairie town" consists of a series of nostalgic reminiscences of a West Texas town of some fifty or sixty years ago. The town is presented through the remarks of the druggist to a traveler. The two chapters remotely related to medicine concern the old time druggist—pillroller—and the old "Doc".

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HYPERSENSITIVITY TO INSECT BITES

To the Editor—I have noticed that shortly after I have been bitten on the hand by a mosquito I develop a typical transitory lymphangitis which itches a great deal and extends at times to the axilla. I do not find any reference to this in the literature. Can you tell me if this is a common occurrence? Is it a manifestation of allergy?

Egon E. Kattwinkel, M.D., West Newton, Mass.

ANSWER—It is not uncommon for persons to demonstrate varying degrees of hypersensitivity to insect bites. The hypersensitive state may develop through contact with the scales from the wings or body of insects, the injection of venom or the introduction of salivary secretions.

Rhinitis and asthmatic attacks have been reported to result from inhalation by sensitized persons of scales and dust from sand flies, caddis flies, various moths and butterflies, bees, wasps, bedbugs and even the house fly.

Braun L. I. Notes on Desensitization of a Patient Hypersensitive to Bee Stings. *South African M. Rec.* 23:408 (Sept. 26) 1925.

Deaths due to anaphylactic shock following bee stings have been reported.

Undoubtedly the reaction to mosquito bites simulating transitory lymphangitis is an allergic phenomenon. Benson (*Arch. Int. Med.*, referred to later), working with mosquitoes, found that in hypersensitive individuals the immediate wheal following the insect bite was insignificant in comparison to the height of the reaction reached in twenty-four to forty-eight hours, at which time a large, slightly raised infiltration appears which persists for several days. These infiltrations may involve the entire arm after a single mosquito bite. Hecht (*Zentralbl. f. Haut u. Geschlechtskr.* 44:241, 1933) reports such a phenomenon following the bite of the mosquito *Anopheles maculipennis*. Brown, Griffiths, Ersin and Dyrenforth (*South M. J.* 31:590 [June] 1938) describe the occurrence of the Arthus phenomenon with mosquito bites.

The results of investigation on the value of extracts of insects as desensitizing agents have shown that the sensitization is species specific for the insect involved and that hypersensitive individuals can be desensitized by a series of inoculations with the specific extract.

PHYSIOLOGY OF DROWNING

To the Editor—What are the physicochemical changes which take place in a drowned human body which cause it to rise subsequently? What time is required for the different phases and is there any difference between salt and fresh water?

L. A. Crowell, Jr., M.D., Lincoln, N. C.

ANSWER—The physiology of drowning was investigated extensively by Paul Bert whose findings were described by Brouardel (*La pendaison la strangulation, la suffocation la submersion* 1897). More recently workers at Banting Institute, Toronto, have reported experimental investigations (Longhead, D. W., Jones, J. M., and Hall G. E. *Physiological Studies in Experimental Asphyxia and Drowning, Canad. M. J.* 40:423 [May] 1939). The physicochemical changes in the body are identical whether produced by drowning or by other types of asphyxiation except that there appears to be some tendency to hyperchloremia when in sea water.

The drowned body floats because of the progressive accumulation of metabolic gases in the body cavities, which finally produce enough of a gradient in specific gravity to float it. The same thing happens if the body is placed in the water immediately after death. In salt water, theoretically, the buoyant force of the water is greater, therefore the body would float earlier. However, so many factors modify the time sequence of reactions that it is doubtful whether there is much practical importance to this point. Some of these factors are the relative amount of fat, the amount of air imprisoned in the clothing, the amount of water that gets into the lungs (many people drown with no water in the lungs because of laryngospasm), the amount of water swallowed into the stomach and lastly the metabolic state of the victim. Any textbook on physiology describing the sequence of events in asphyxiation will give the inquirer the full details, which are too extensive for inclusion here.

SIMULTANEOUS USE OF GOLD AND VITAMIN D FOR RHEUMATOID ARTHRITIS

To the Editor—Has any work been done on the treatment of rheumatoid arthritis using both intramuscular gold salts and high dosages of vitamin D at the same time? My practical question is: Are the hazards in the use of the former enhanced by active mobilization of calcium? Should the dosage of the gold be reduced during intensive vitamin D therapy or could the two be used safely in full dosage together?

C. S. Shuman, M.D., Black River, N. Y.

ANSWER—Special studies have not been conducted to determine the value of treatment of rheumatoid arthritis employing large doses of vitamin D together with gold salts. There is no evidence that the toxicity of gold is increased by administration of vitamin D in large amounts. The intermediate metabolism of gold is not well understood. Whether alterations in calcium and phosphorus metabolism, should they occur as a result of vitamin D therapy, would affect the metabolism of gold is not known. Various attempts have been made to alter the metabolism of gold in a way similar to the manner in which lead metabolism is affected, but all of these attempts have been unsuccessful. In the present state of our knowledge there seems to be no reason to employ smaller amounts of gold because vitamin D is used simultaneously. Because each of these preparations independently may cause toxicity, should gastrointestinal symptoms or vague neuromuscular symptoms occur, it may be difficult to know which drug is causing them.

BALL PESSARIES

To the Editor—Would you please discuss the use of ball pessaries, their indications and relative value as compared to other nonoperative measures? Where can I find references and instructions how to fit them?

M. D., New York

ANSWER—Ball pessaries were formerly rather widely used for palliative relief of patients with cystocele and uterine prolapse. The ball is usually hollow, the size of a golf ball or larger, and commonly made of celluloid or plastic material.

Insertion is a simple matter, and the ball usually holds a uterus perfectly provided there is sufficient perineal support. Even in apparently satisfactory cases however, the ball may fit too tightly. Curtis in his *Textbook of Gynecology*, second edition, records having been called on several times to remove one of these pessaries and in two instances required gas anesthesia to remove a ball which had been easily inserted by the family doctor.

The Menge pessary or Gellhorn's modification of it or the Emmet-Gellhorn pessary is much more satisfactory for the nonsurgical care of cystocele and uterine prolapse. Illustrations of these instruments and the technic of their use are available in standard textbooks of gynecology.

PROGRESSIVE MYOPIA IN CHILDREN

To the Editor—Is there any relation between progressive myopia in children and hypothyroidism? Some eye specialists feel that children exhibiting progressive myopia should receive thyroid unless their basal metabolic rate is on the plus side

M D California

ANSWER—The only evidence in favor of any relation between progressive myopia and hypothyroidism seems to be in a report by Bothman, who found slightly lowered metabolism in some cases. This does not seem to have been confirmed by other observers, and the reliability of computing metabolism in children has been brought into question. Most ophthalmologists feel that proof of any such relationship is insufficient. This writer has checked metabolism in a number of cases without finding any evidence of hypothyroidism. An article by Cowan in the *American Journal of Ophthalmology* for July 1942 expressed the opinion held by a large group of ophthalmologists, which is that myopia is a growth phenomenon without any relation to endocrine disorders or any systemic disease and that it is not affected by local or systemic treatment.

TAME RABBITS AND PLAGUE

To the Editor—I have had many recent inquiries about the plague black death. Please inform me if tame rabbits constitute a menace in the spread of this disease.

W Calvin Jones M D Pampa Texas

ANSWER—Yes, if the rabbits are in an infected territory. Plague infection has been proved in the tissue of cottontail rabbits in nature, in fleas from these rabbits and in tissue from jack rabbits and brush rabbits. Dr B J Lloyd of the U S Public Health Service (retired) states that a pet rabbit died of plague in the same house in which he lived in Guayaquil, Ecuador. A campaign of extermination had been conducted against the rats. While the important rat flea vector of plague prefers rats it will also feed on other animals, especially when its favorite host is not available. If plague is present in the vicinity tame rabbits are in element of danger in spread of the infection, if not they constitute no menace.

USE OF CYCLOPLEGICS IN REFRACTIONS

To the Editor—It was brought to my attention by one of the optometrists working in the camp hospital that the majority of the better ophthalmologists in the United States no longer use a cycloplegic as a routine refraction aid. I would appreciate learning the true facts in this regard.

Major, M C U S Army H L Folk M D Camp Haan Calif

ANSWER—Thirty years ago the ophthalmologists of this country were using cycloplegics routinely in refraction in about 5 per cent of their cases. Today, particularly in the larger cities, similarly trained ophthalmologists are using cycloplegics routinely in about 90 to 95 per cent of their refractions regardless of the age of the patient. There are two definite reasons for this. In the first place the refraction is much more accurate, particularly for younger people, among whom accommodation plays a role. In the second place patients come to ophthalmologists for a thorough examination of their eyes, a procedure that is not completely possible without dilatation of the pupils.

TREATMENT OF SYPHILIS IN PATIENT WITH CARCINOMA

To the Editor—A man aged 54 who has carcinoma of the tongue has received radium treatments but still complains of pain as the area which was treated is ulcerated and not completely healed. His Wassermann reaction is 4 plus but because of living in the country on a ranch and not having the facilities to drive into town he has discontinued his antisyphilitic therapy. I feel that his mouth condition from the standpoint of healing might be bettered if he was taking antisyphilitic therapy. Would you be so kind as to tell me whether sublingual mass would be indicated in such a case and would it be beneficial, or what type of antisyphilitic therapy (which would have to be oral) could be given this man? Will you kindly give me a procedure of treatment using the oral preparation which you deem best?

M D New Mexico

ANSWER—At present there are no drugs that can be used orally in the successful treatment of syphilis. Neither does it seem essential to treat the syphilis in the case described because at the moment the carcinoma of the tongue is the paramount issue. The only need for such treatment would be if the lesion on the tongue was gummatous rather than carcinomatous. If the malignant condition is controlled, it might then be advisable to institute antisyphilitic treatment of a mild nature, and the use of a bismuth compound given intramuscularly in small doses would probably be the most satisfactory treatment for the syphilis in this instance if there are no other manifestations of the disease that required intensive therapy.

'MEMBRANE' IN EXTERNAL AUDITORY CANAL

To the Editor—I have had occasion routinely to examine many ears both under normal conditions and after the washing out of a plug of ear wax. Particularly after washing but occasionally too in the unwashed ear I have noticed the remains of a membrane stretching across the middle third of the external auditory canal whose plane is approximately parallel to that of the drum membrane. It is rare to find this membrane intact rather one observes the remaining half or third of it or else its broken detritus lying on the floor of the external auditory canal. However on two occasions the membrane remained almost intact and once a small rent in it gave rise to the mistaken diagnosis by a colleague of a perforation of the tympanum. I have not seen mention of this membrane (which I called false tympanum for want of a better name) in textbooks and should like to know if it is recognized and by what name.

M D, New York

ANSWER—The skin of the external auditory canal, like the integument elsewhere, constantly loses its most external layers. Any condition which allows the desquamated cells to remain in the canal may be responsible for the appearance of false tympanic membranes. This is particularly true in the presence of hard impacted cerumen, which acts like a mold to shape the cast off epithelium.

Neither Politzer who is said by some to have seen and noted 'everything,' nor the *Handbuch* of Denker and Kahler makes any specific remarks concerning the condition described.

ACCOMMODATION DURING PREGNANCY

To the Editor—It has recently come to my attention that some of the public and also obstetricians feel that glasses fitted during pregnancy may not be suitable after parturition. As I cannot find any references what is your opinion as to whether the refractive error or index of refraction does change?

M D, Denver

ANSWER—Changes in the actual refraction of the eye during pregnancy unaccompanied by ocular disease have not been noted. However, it is well known that disturbances of accommodation do occur not infrequently probably because of generalized muscular weakness and simulating a premature presbyopia. Glasses to correct that condition would no longer be suitable after parturition. Actual disease of the eye with resultant decrease in vision due to ocular disease is not uncommon. An extensive discussion of this subject may be found in the old *American Encyclopedia of Ophthalmology*, volume VIII.

CONVULSIONS AND UNCONSCIOUSNESS FROM HYPOGLYCEMIA

To the Editor—What is the frequency of clonic convulsions in hypoglycemia attended with loss of consciousness? How low does the blood sugar drop and is there any premonition of its approach? Without laboratory aid are there pathognomonic signs to differentiate epilepsy and hypoglycemia?

J Eugene Kraft M D, Rochester N Y

ANSWER—While a statistical frequency cannot be stated for clonic convulsions with loss of consciousness in hypoglycemia it is a not infrequent occurrence. The critical level of hypoglycemia at which symptoms begin to be observed is usually given as 40 mg per hundred cubic centimeters. However, it is generally agreed that hypoglycemic manifestations are not strictly related to the absolute level of the blood sugar but are rather a function of the rapidity of the fall in the blood sugar level. Premonitory signs and symptoms of impending hypoglycemia are the rule but their particular nature for a given patient is a highly individual matter, although they are usually a constant characteristic in that person. Without laboratory aid there are no pathognomonic signs to differentiate attacks of hypoglycemia from epilepsy.

SILICOSIS AND THE HEART

To the Editor—I am much interested in the communication in *The Journal*, Sept 26, 1942, page 326, with reference to silicosis and the heart. I am satisfied that the relationship between pulmonary fibrosis such as obtains in silicosis and cor pulmonale has been insufficiently recognized. This is true not only of clinical investigations but in many instances of post mortem studies. I believe that many patients with silicosis die of heart failure and this is substantially recorded in the literature. The distinction between simple discrete silicotic nodulation as affecting the heart and more massive fibrosis is not a sound one if it is based only on clinical and x-ray studies. I have many cases in my own experience of death from right heart failure in cases of silicosis that were diagnosed during life as uncomplicated nodular silicosis. Whether or not the symptoms obtaining in silicosis are cardiogenic secondary to pulmonary disorder or primary cardiogenic depends a good deal on the care and extent of the clinical investigation and the thoroughness with which the physician applies present day knowledge of the interrelationship between pulmonary and cardiogenic disorders.

Norbert Enzer M D, Milwaukee

PRESENT STEPS IN CONTROL AMONG
CIVILIAN GROUPS

With venereal disease control becoming more and more difficult and with an unavoidable shortage in professional personnel, what steps can be taken to maintain adequate control in the civilian population?

We have a framework of organization and administration on which to launch an all out attack. Each of the forty-eight states has in effect a cooperative control program with the Public Health Service. Although funds budgeted in the fiscal year 1942 were about the same as in 1941, control activities for the first half of 1942 exceeded those of the same period in the previous year.

The following figures indicate some advance. Reports from private physicians and clinics increased almost 3 per cent. The distribution of arsenical drugs increased 2 per cent, and the number of blood tests for syphilis 1 per cent. Blood tests are now being made at the rate of more than seventeen million a year.

More encouraging are the results of measures taken to control gonorrhea among the civilian population. Sulfathiazole and sulfadiazine are proving to be remarkably effective in the treatment of gonorrhea. Results obtained from widely separated sources indicate that these drugs can effect cures in about 90 per cent of the cases in as short a period as two weeks. As with syphilis, reporting and treatment of cases seem to be on the increase. The number of cases of gonorrhea reported to health departments in the first half of the fiscal year 1942 has increased 11 per cent and the distribution of sulfonamides 60 per cent.

The routine blood testing of all candidates examined under the Selective Service and Training Act has presented us with the greatest opportunity to date for the control of syphilis in the civilian population. Today, as a result of the tests made by private physicians and the cooperating state health department laboratories, 200,000 men presenting evidence of syphilitic infection have been discovered.

The responsibility of following up infected individuals found in the routine blood testing of Selective Service candidates has fallen on the local health departments, many of which are not yet prepared to undertake such an intensive campaign. Current reports indicate that approximately 60 per cent of the cases reported in the Selective Service examinations have been investigated and that more than 40 per cent of these have been placed or found under treatment. As might have been expected, follow-up and rehabilitation are being achieved, for the most part, in those states where adequate venereal disease control facilities are available.

The great opportunity for the control of syphilis, however, lies in tracing and bringing under treatment the exposed contacts of men found infected in Selective Service examinations. In most states, little or no action has been taken to uncover the sources of infection and the contacts of these infected men.

The states have been greatly handicapped on the one hand by the depletion of their professional staffs and on the other by the enormous increase in demands for all types of public health service. Many state and local health departments are working overtime under the depressing knowledge that their contribution to venereal disease control is both "too little" and "too late." They know that many infectious cases are not being reached in time to prevent the transmission of disease. Other health departments remain apathetic to the problem of venereal disease control.

With emergency funds appropriated by Congress, the Public Health Service has recruited more than seven hundred professional personnel and assigned them to state health departments for duty in critical war areas. Many of these are carrying on venereal disease control work in new mobilization centers as a part of the generalized public health program. Venereal disease control officers and nursing consultants are on duty in each of the nine district offices of the Public Health Service. Liaison officers of the service in the nine army corps areas are also devoting much of their time to the problem of venereal disease control in extracantonment communities. In addition, more than one hundred medical officers and other professional personnel of the service are now devoting full time to venereal disease control work.

Despite advances in organized control work, despite the significant contribution of the Selective Service examinations to case finding, we are still far from positive control of syphilis and gonorrhea in critical areas. In February of this year the Congress recognized the urgent need for intensified venereal disease control activity as a part of the nation's war effort. The sum of \$2,500,000 was made available by a deficiency appropriation. On April 1, under the provisions of the Venereal Disease Control Act, the states received additional funds to meet war needs.

Although there has not been sufficient time to permit a detailed report on how these funds are being utilized by the states, the first need to be met is the employment of all available trained personnel. By this means it will be possible for the state laboratories to meet the accelerated pace of blood testing in connection with Selective Service examinations. With the expansion of the Army to six million by the end of 1943, as announced by the government, the laboratories will experience unprecedented demands.

These funds will also facilitate the follow-up and rehabilitation of men found infected with venereal disease in the Selective Service examinations and their subsequent referral to their local boards.

More important still, improvement can be expected in bringing to treatment civilian contacts of these men and of infected military personnel. Although local health departments need money and personnel to carry on this vital control activity, it should be remembered that success depends on the cooperation of the private physicians, the personnel of private clinics and the military authorities in furnishing health departments with the information obtained from patients as to sources of infection.

The present shortage of professional personnel demands that every means be adopted to utilize the available supply to the best advantage. One effective measure, now being applied in many professional fields, is the employment and training of lay workers to supplement the professional staff. In venereal disease control work this system has already been tried and found effective.

Plans are under way to increase the employment and training of lay personnel for follow-up work under the supervision of professional staffs. In this way it should be possible to find more civilian sources of infection and bring more contacts to examination and treatment.

HOW TO CHECK VENEREAL INFECTION

The war will bring to the physicians who remain in their communities overwhelming tasks comparable with the experiences of our colleagues in the Army and Navy.

One of the first tasks commanding the doctor's attention is the control of venereal diseases in his community. No matter how well we plan and execute a national attack, no matter how far we stretch the available funds, the control of these diseases is in the hands of the local physicians of the United States. Neither the federal government nor the local health department nor the private physician, however, can accomplish this great task alone. Together, we can bring venereal diseases under control and keep them under control. The formula appears to be simple: find the early cases, get them under treatment, keep them under treatment. We know that the simplicity of the medical aspects which concern physicians directly is greatly complicated by social, economic and war conditions. If every physician holds fast to that simple plan of action, if every physician meets every case of venereal infection that comes to his attention with a determination to see it through, the threat of venereal diseases to our national strength will be held in check as never before, and at a time when our total strength is needed.

ABSTRACT OF DISCUSSION

DR JOHN H. STOKES, Philadelphia. When war enters the venereal disease control scene, not only does venereal disease increase but the long range elements of control move up so that one is compelled to fire point blank arms and ammunition. It would have taken years to aim and fire in ordinary circumstances. As Dr Aselmeyer emphasizes, a state city or any other group which has not built up laboratory and clinical facilities in advance will have a bad time. It will take a year to standardize the laboratories of a populous state, and the clinical facilities, as indicated by the discussion of the housing problem, will be shot to pieces by the population shift and springing up of boom towns. The next job is to arouse the public. To reach the public, go to key men in each social group who will do something about particular things. Our public education program in Philadelphia got under way after initial rebuff, through two men: one of whom got us on the air, the other into the street cars. Next try to rouse the doctors. Worse than busy, worse than worried, depleted in numbers and threatened by this and that, real or imagined, the physician is the only man you cannot get to join actively in venereal disease control work. We shall yet have to train technicians to shoot the drugs, get a doctor to stop in to see that they are not being fired in the wrong direction, throw the bulk of our effort into night clinics and so on. The pharmacist realistically considered is the forefront of venereal disease control in civil life. A copy of our state advisory committee's "Appeal to Pharmacists," referred to in *THE JOURNAL* June 6, can be made available to you. The pharmacist in Philadelphia is spreading public information. He has backed our civil prophylaxis experiments (packet prophylaxis) and will, we believe, steer patients into clinics and physicians' offices. Of the industrial situation in civilian venereal disease control, our experience has been that the stymie is not with the industrialist but too often with the medical industrial group or the personnel and budget authority. In other words, this is a government proposition and not a civil one. Somebody ought to decide pretty soon who is to do it and do something. Basic law under which enforcement action is taken is aimed at the formally defined prostitute who solicits and asks a price. The old time prostitute in a house or the formal prostitute on the street is sinking into second place. The new type is the young girl in her late teens and early twenties, the young woman in every field of life who is determined to have one fling or better. Such relations are outside the legal control framework entirely and can be reached only by an efficient contact tracing mechanism and persuasion methods. The carrier and disseminator of venereal disease day is just one of us, so to speak.

DR CHARLES M. CARPENTER, Rochester, N. Y. I should like to ask Dr Stokes what the reaction of the physicians in Philadelphia is to this program that the pharmacist is sponsoring.

DR N. O. GUNDERSON, Rockford, Ill. I should like to know how it could possibly be made easier for physicians to report sources of infection. They hesitate to put them on the definite reports in writing.

DR THEODORE ROSENTHAL, New York. In New York City confidential case reports of venereal disease have a definite space for information as to the source of infection of the patient. In practice more often than not this specific information is omitted from the case report, however, in all reported instances of communicable venereal disease, that is, primary syphilis, secondary syphilis, early latent syphilis and acute gonorrhea, when such information is omitted from the case report the reporting physician is immediately reached, either by telephone or in person by a health department representative, and the information requested. When the physician can supply the information, he will do so. Occasionally the physician will, and as a matter of fact has, permitted the health department epidemiologist to interview the patient in his own office, often in the guise of a professional associate or consultant to the treating physician. I should like to refer briefly to our relations with the pharmacist in New York City where there are over four thousand retail pharmacies. The health department has labored with organizations of retail drug groups for many years. Five or six years ago we secured the cooperation of the various associations to put into their stores counter and window displays giving brief information on syphilis and gonorrhea. In addition, with the further cooperation of these groups the health department got out a special edition of a basic information pamphlet for the public on syphilis and gonorrhea, with an imprint stating that it was distributed through the courtesy of the organized pharmacists of the city. Large quantities of these leaflets were placed on the counters alongside the counter displays. We have always believed that the use of an advertising card in rapid transit coaches and street cars would be of great importance as a health education medium.

DR CHARLES WALTER CLARKE, New York. An important event has taken place with regard to some of the background problems involved in the control of venereal diseases. There was passed about a year ago an act called the May Act, a federal statute which empowered the Secretary of War and the Secretary of the Navy to create a zone around any army or navy establishment within which the practice of prostitution or aiding and abetting the practice of prostitution became a federal offense. Now for the first time such a zone has been created. This is an important advance, because it shows to those who are making a business and profit out of prostitution that the federal government is really very much in earnest in its intention to protect soldiers and sailors from the dangers of prostitution. An area was set up in Tennessee and comprises twenty seven counties extending in a broad band from just north of Nashville to Chattanooga. It doesn't include Chattanooga because that city and county were, as a matter of fact, doing a very good job in the repression of prostitution. Dr Stokes makes a very good point in saying that the form of prostitution has changed in a great many places. It has changed particularly in our Northern and Eastern cities, however, the old fashioned type of prostitution in brothels is still extant and still constitutes a very serious problem in some parts of the country. I have figures from one particular place where the sources of infection of a large group of soldiers were traced and found to be 82.5 per cent in the houses of prostitution, and the extraordinary thing was that the health department of the city in which these brothels were located carried out a health inspection of every prostitute once a week. This, I think, has some significance.

DR A J ASELMAYER, Washington, D C I want to thank Dr Stokes and the other gentlemen for their very helpful suggestions in regard to the solution of the problems which must be met. The pharmacists are cooperating with a number of state health departments, in addition to the city of Philadelphia, at least to the extent of putting displays in their windows and directing applicants for remedies for treatment of venereal disease to clinics or private physicians and by pledging not to sell remedies direct to the customer. I was glad to hear Dr Stokes's remarks on the use of prophylactics and the need for extending and interpreting their use to the civilian population. This is being tried in one area on a demonstration basis at present, in cooperation with the Public Health Service and the city health department. The alcohol distributors in a number of states are insisting that their retailers do not have any rooms for rent anywhere on or near about the premises. If they do have, their licenses are revoked. In regard to Dr Carpenter's question, Dr Stokes tells me that the physicians are at least not opposed to the use of pharmacists. They are somewhat interested but seem to be so busy and have so many other things to do that they don't seem to react very much to it one way or the other. I want to thank Dr Clarke for mentioning the progress made in the repression of prostitution.

THE METHOD OF NASOPHARYNGEAL CULTURE IN THE DIAGNOSIS OF WHOOPING COUGH

ANNE MORRIS BROOKS, M S

WILLIAM L BRADFORD, M D

AND

GEORGE PACKER BERRY, M D

ROCHESTER N Y

In a previous report¹ attention was called to the superiority of the nasopharyngeal culture to the customary cough plate culture when the two procedures were simultaneously tested in a group of 25 patients with whooping cough. In the present paper we wish to present the data collected in a further comparative study of these methods.

The majority of the cultures were obtained from infants and children in the contagious division of the Rochester Municipal Hospital. Some were obtained from patients in the outpatient department and a few from private patients and from persons referred to the Rochester health bureau laboratory for diagnosis. Only 3 adults were included in the series.

The swab for culturing the nasopharynx was prepared by tightly wrapping a small bit of cotton about the end of a piece of flexible copper wire $6\frac{1}{2}$ inches² in length (fig 1). The prepared swab was placed in a pyrex test tube (5 by $\frac{5}{8}$ inches) and the tube, plugged with cotton, was sterilized in the autoclave.

A nasopharyngeal culture was taken by gently passing the swab back through the nares until it touched the

posterior nasopharyngeal wall. Culture was taken from only one side of the nose. If an obstruction was met on one side, the swab was withdrawn and inserted into the opposite nares. With a little experience, the culture was rapidly obtained and with practically no discomfort to the patient.

To inoculate the medium a drop of 0.85 per cent solution of sodium chloride was placed on the surface of Bordet medium, near one edge, and the material from the swab gently mixed into the drop of saline solution. Streaking was then carried out with a flexible platinum loop. The streaked plate was incubated for seventy-two hours at 35 C.

The cough plates used for comparison with the nasopharyngeal cultures consisted of Bordet medium in a small Petri dish (2 inches in diameter) which was contained in a metal salve box. The plate was held in place in the box by wedging a small piece of cork between the dish and the side of the box (fig 1). This container was relatively nonbreakable and could be easily carried about in the physician's pocket. After incubation, the half of the Petri dish containing the medium was removed from the metal box making it easy to observe the hemolytic zones about the colonies of *Hemophilus pertussis*. We have found this type of cough-plate assembly distinctly superior to the usual Petri dish or the salve box as a container for the medium for it preserves the advantages but excludes the disadvantages of each.

The composition of the medium³ has been previously described.⁴ It consists of a potato extract base to which has been added freshly collected, defibrinated sheep blood.

On this medium *Hemophilus pertussis* appeared after forty-eight hours of incubation at 35 C as small convex smooth glistening colonies resembling tiny drops of mercury. At the end of seventy-two hours of incubation a zone of incomplete hemolysis was present about the colony. On the streaked plates almost pure cultures of *Hemophilus pertussis* were frequently obtained from nasopharyngeal swabs (fig 2). All strains were further identified by the rapid agglutination method of Kendrick.⁵

RESULTS

A total of 438 nasopharyngeal cultures was taken from 248 patients with pertussis and 198 cough plates were made in 157 cases. More than one culture was frequently obtained from each patient. In certain instances, in hospitalized patients cultures were taken two or three times a week. The results of the comparative study of the nasopharyngeal and the cough plate methods have been tabulated on the basis of total cultures and of primary cultures taken. They have also been compared on the basis of age.

3 The base was made as follows

Peeled potato	500.0 Gm
Glycerin (U. S. P.)	40.0 cc
Agar (Bacto)	120.0 Gm
Sodium chloride (chemically pure)	21.5 Gm
Distilled water	4,000.0 cc

To the melted and cooled base was added 10 per cent of defibrinated sheep blood. After being mixed the mixture was poured into Petri dishes. The plates were kept at 4 C. They were discarded when 4 days old.

2 The wire known as trolling line was obtained from Sears Roebuck & Co.

More nasopharyngeal than cough plate cultures were taken (table 1). This was especially true among the infants, whose cough was often more "hacking" than explosive in character and in whom it was frequently impossible to stimulate a paroxysm when a cough plate

Fig. 1—Materials for the nasopharyngeal and cough plate methods of culturing *Hemophilus pertussis*.

was to be exposed. In 45 instances satisfactory cough plate exposures could not be obtained, although nasopharyngeal cultures taken on the same occasion, were positive. Occasionally older children were not able to cough when brought to the clinic, in which instances only nasopharyngeal cultures were made.

A survey of all the cultures made, disregarding age, showed that in a total of 438 nasopharyngeal cultures 52 per cent were positive, while in a total of 198 cough

however, compares favorably with that (24) obtained when primary cultures only were analyzed (table 2). There was a greater difference between the groups during the early weeks of the disease, at a time when a prompt diagnosis is most important because of the high degree of infectivity. The lower percentage of positive cultures obtained during convalescence was to be expected. Further analysis of the data revealed that in 211 (85 per cent) of the 248 cases of pertussis the clinical diagnosis was confirmed by either primary or repeated nasopharyngeal cultures. In certain cases of mild involvement a definite diagnosis would not have been possible without recovery of the organism from the respiratory tract.

TABLE 1—Total Number of Cultures. Results of Four Hundred and Thirty-Eight Nasopharyngeal and One Hundred and Ninety-Eight Cough Plate Cultures

Week of Disease	Nasopharyngeal Swab Method			Cough Plate Method		
	Total Number of Cultures	43 Cases		Total Number of Cultures	197 Cases	
		Number Positive	Per Cent Positive		Number Positive	Per Cent Positive
1st	60	48	80	31	14	45
2d	11	87	6	75	36	48
3d	91	55	61	59	17	29
4th	20	15	75	14	3	21
5th and on	101	51	50	59	3	5
Totals	438	250	57	198	43	22

Difference in percentage = 35 standard error = 4, ratio = 3.5 to 1

TABLE 2—Primary Cultures. Comparison of the Nasopharyngeal and the Cough Plate Method

Week of Disease	Nasopharyngeal Swab Method			Cough Plate Method		
	Total Number of Cultures	Number Positive	Per Cent Positive	Total Number of Cultures	Number Positive	Per Cent Positive
1st	60	49	81	0	14	47
2d	11	12	72	53	3	47
3d	91	55	61	59	13	22
4th	21	5	24	12	2	17
5th and on	28	3	11	20	1	5
Totals	215	124	57	157	33	21

Difference in percentages = 24 standard error = 4.9 ratio = 4.9 to 1

Data relating to primary cultures only are shown in table 2. Primary cultures were positive much more frequently by the nasopharyngeal than by the cough plate method.

A more accurate assessment of the value of the nasopharyngeal method was possible when simultaneous cultures were made by the two methods on the same patient. One hundred and eighty-three simultaneous cultures were taken from 165 patients (table 3). One hundred and five (57 per cent) of these were positive by the nasopharyngeal method while but 62 (34 per cent) were positive by the cough plate method. This difference of 23 per cent is statistically significant, because the ratio of this difference (23) to its standard error (5.0) is 4.6 to 1. Ninety (48 per cent) of the 183 simultaneously taken cultures were positive only by the nasal method, while 21 (11.4 per cent) were positive

Fig. 2—Seventy-two hour growth of *Hemophilus pertussis* showing an almost pure culture obtained by the nasopharyngeal method.

plate cultures 37 per cent were positive (table 1). Since factors such as repetition of cultures, age of the patients and stage of the disease when the cultures were taken were not evenly balanced in the two groups, accurate comparison of the results was not possible. The difference in the percentages of positive cultures (15),

by the cough plate method alone—a finding which suggests that the combined method of culturing would give the optimal positive results

The superiority of the nasopharyngeal method was still more apparent when the patients were grouped according to age. The results (table 4) indicated a difference of 48 per cent in the number of positive cultures obtained by the two methods during the first two weeks of the disease. Regarding the total of 106 simultaneous cultures taken from 88 patients, 57 per cent were positive by the nasopharyngeal method as compared with 25 per cent positive by the cough plate method, a difference of 32 per cent. The ratio of this difference (32) to its standard error (6.4) is 5 to 1, indicating clearly that this difference is significant.

Even when simultaneous cultures made on older children were analyzed (table 5), there were significantly more positive cultures obtained by the nasopharyngeal method during the catarrhal period. The difference observed for the entire series, however, was not statistically significant, as indicated in the table.

Although these results indicate that the nasopharyngeal culture method is definitely superior to the cough

We believe that this technic will give satisfactory results if the medium is inoculated within twenty-four hours after the swab culture is taken.

Thus we have found the nasopharyngeal method useful in studying the survival of *Hemophilus pertussis* in

TABLE 4—*Simultaneous Cultures from Patients Under Three Years of Age. Comparative Results of One Hundred and Six Cultures Taken from Eighty-Eight Patients*

Stage of Disease	Total Number of Cultures	Nasopharyngeal Swab Method		Cough Plate Method

the nasopharynx during whooping cough, and, on one occasion, in an investigation of an epidemic of paraper-tussis occurring among children attending a day camp.

SUMMARY

A total of 438 nasopharyngeal cultures from 248 cases of pertussis and 198 cough plate cultures from 157 cases were taken. Fifty-two per cent of the nasopharyngeal cultures and 37 per cent of the cough plate cultures were positive.

In a series of 248 primary nasopharyngeal cultures, 152 (61 per cent) were positive as compared with 58 positive (37 per cent) in a group of 157 primary cough plate cultures.

When 183 simultaneous cultures were made by the two methods in 165 cases of pertussis, 105 (57 per cent) were positive by the nasopharyngeal method and 62 (34 per cent) were positive by the cough plate

TABLE 5—*Simultaneous Cultures from Patients Over Three Years of Age. Comparative Results of Seventy-Seven Cultures Taken from Seventy-Seven Patients*

method. This difference (23 per cent) was statistically significant. The difference was even greater when data obtained by cultures from infants under 3 years of age were analyzed.

CONCLUSIONS

The method of nasopharyngeal culture is superior to the cough plate culture method for the diagnosis of whooping cough, particularly in infants.

plate method for the laboratory diagnosis of pertussis, we recognize the fact that the newer method requires more extensive testing. The results obtained recently by Miller and his associates⁶ constitute an encouraging confirmation of our observations. Further testing, particularly under conditions of a field study, should be made. This is especially desirable because it is highly probable that the ever increasing number of cases of mild and atypical pertussis resulting from the modifying effect of vaccine presents a definite demand for better methods of laboratory diagnosis.

In our hands, recent preliminary experiments have shown that the nasopharyngeal method gives reliable results for field work if the swab is kept moist. By keeping the charged swab suspended in a test tube containing a bit of rubber sponge wet with 0.85 per cent solution of sodium chloride and by keeping the tube plugged with a rubber stopper (fig. 1), the swab will remain moist for ninety-six hours. Of 17 swabs inserted into the nasopharynx of patients with pertussis, 15 were positive after being held for twenty-four hours at room temperature in this type of container. In 2 instances they were positive after forty-eight hours.

NEW YORK

We have undertaken a clinical and immunologic study involving the antitoxin immunity actively induced and passively conferred in well and in ill children based on the fact recently demonstrated by Merritt Roberts¹

ing the organisms. They did not demonstrate its antigenicity and termed it endotoxin. Other investigators, notably Tessier and his co-workers,³ Lawson⁴ and Roberts,¹ demonstrated that such extracts were antigenic. Subsequently washings from whole organisms and broth mediums in which the organisms had grown were found by Evans⁵ and Mishulow⁶ to be toxic and to produce antitoxins. Mishulow and later Koplik demonstrated, by the Schwartzman phenomenon, a toxin in some cultures of *H. pertussis*. Sprunt⁸ produced identical pneumonic lesions by intratracheal injections of bacilli (living and dead) and of toxin in normal mice, rabbits and monkeys which were prevented by antitoxin. Merritt Roberts recently offered evidence to show that the toxic filtrate or endotoxin and exotoxin were identical and that the two produced a neutralizing antitoxin. The exotoxin obtained in broth cultures and the endotoxin from bacterial extracts have been shown to be identical in four respects: heat stability, lethal power in mice, necrotizing effect on the skin of

Chart 1—Antigen titer of children given injections of 300 units of pertussis toxin per cubic centimeter of antigen. The total dose is 6 to 5 cc in four weekly injections. Titer increased 22 children (68.75 per cent), titer unchanged 6 children (18.75 per cent), 3 had temporary increase, titer decreased 4 children (12.5 per cent). Among children under 1 year titer increased in 8, was unchanged in 1 and decreased in 1. In charts 1, 4 and in chart 7 the black dot indicates initial and final titer in each case; dashes, initial titer unchanged; white dot, average change; caret pointing to left, less than 0.3; arrow pointing up, vaccine administration or antigen administration as the case may be; Y, years; M, months.

that endotoxin and exotoxin of *Hemophilus pertussis* are identical and on the fact previously demonstrated that this toxin is antigenic. Bordet and Gengou extracted a toxic substance from *H. pertussis* by grind-

ing the organisms. Both are capable of antibody production.

These studies were conducted mainly in the wards of the Willard Parker Hospital with the assistance of the resident physicians, on siblings of patients admitted there, and at the Central Harlem Health Center.

ACTIVE IMMUNIZATION WITH TOXOID
PROPHYLAXIS

One hundred and thirty-five unselected children living at home were given prophylactic injections. One hun-

Read before the Section on Pediatrics at the Ninety Third Annual Session of the American Medical Association Atlantic City N. J. June 11 1942.

Drs. Katona and Scannell are resident physicians at the Willard Parker Hospital and Drs. Alterman and Robinson are Littauer fellows at the Harlem Hospital.

From the Littauer Pneumonia Research Fund of New York University College of Medicine. These studies received additional support from Mr. Bernard M. Baruch, Mr. Bernard M. Baruch Jr., Miss Belle W. Baruch and Mrs. H. Robert Samstag.

Dr. Merritt Roberts of Pearl River, N. Y. performed the rabbit skin titrations. The antitoxin was prepared in the Lederle Laboratories, Inc. Pearl River. It and the toxoid were furnished by Dr. W. G. Malcolm. Dr. H. T. Fuerst assisted with some of the injections. The observations at the Central Harlem Health Center were made with the permission of the commissioner of health, Dr. John L. Rice, and the cooperation of its personnel.

group Nine attacks were severe at onset. No decided clinical improvement was noted in any case. In only 2 cases in which antitoxin was given eight and nine days after onset was a slight improvement observed.

Four cases have been chosen to illustrate the considerable rise in antitoxin titer which may be secured

units was given on three occasions. The antitoxic titer of her blood rose promptly to more than 100 units, and this level was maintained for twenty days. Another child, aged 2½ years, received massive doses, and the antitoxic titer rose to more than 400 units. In eleven days the titer had fallen 81 per cent. In 2 children aged 5 and 2 years respectively, who received smaller doses of antitoxin and whose serum antitoxic titer rose to 10 and 5 units respectively, the fall was 51 per cent in about twenty days. It appears that the administration of extremely large doses of antitoxin may be unnecessary and wasteful (chart 7).

BLOOD ANTITOXIN TITER

Chart 4—Antigen treated pertussis patients with 300 units per cubic centimeter of antigen, total dose 6 to 8 cc. Titer increased 4 children, titer decreased 3 children, titer unchanged 5 children.

Chart 6—Prophylactic antitoxin injections. Solid line represents a sibling exposure before injection, dotted line a sibling exposure after injection, black dot a sibling admitted to Willard Parker Hospital, exposure discontinued, black triangle onset of pertussis. Under 6 months 8 cases, from 6 to 12 months 1 case, from 1 to 5 years 13 cases, over 5 years 3 cases.

following injection of antitoxin. The antitoxic titer was usually maintained above 4 units per cubic centimeter for over twenty days. To 1 of the children, aged 20 months, more than a quarter of a million

were severely stricken. As a control, the siblings of 25 pertussis patients admitted to Willard Parker Hos-

¹² Since this report was read (a) more children have been protected with 1 cc of antitoxin for upward of three weeks. (b) a child exposed for six weeks developed pertussis.

PROPHYLACTIC ANTITOXIN

To another group, 25 exposed children, antitoxin was given to prevent pertussis. The antitoxin was administered intramuscularly on alternate days. The dose varied with the age of the child and the degree of exposure. A total of 10 cc of antitoxin was the maximum given any child.¹² The children in this series were observed from July 1941 to April 1942. The incidence of pertussis during this time was high in our community. Seventeen of the 25 children remained in family contact with patients to whom they were exposed, even after prophylaxis. This type of exposure provides a severe test. In all but 7 instances the patient with pertussis was observed by one of us to whoop. In the evaluation of the results, a child was completely protected or the prophylaxis was considered unsuccessful.

The age of the exposed children given antitoxin ranged from 18 days to 7 years, with 19 children, or 76 per cent, under 5 years. Children can acquire the disease up to forty days from the beginning of exposure but rarely after the first four weeks. We have considered that children exposed beyond six weeks without contracting the disease are immune, and these were not immunized.¹³ The usual duration of exposure before prophylaxis was ten days. Of the 25 children given antitoxin, only 1 child contracted the disease. This was a 14-month-old child who was given injections on the twenty-first and twenty-third days of disease with 2 cc of antitoxin and who developed a mild pertussis starting in the third week afterward. The exposure was to 2 older siblings who

be reasonable to assume that neutralization of this product by antitoxin interferes with the normal life of the organism and hence inhibits the development of the disease

CONCLUSIONS

1 Pertussis antitoxin has been shown capable of preventing whooping cough when given early in the incubation period and prior to onset of cough, even though exposure continues

2 Pertussis antitoxin is of little value in reducing paroxysms when the disease is established with a propulsive cough. Its evaluation in earlier stages is still under investigation

3 Vaccine and toxoid are capable of increasing the pertussis antitoxic titer in the blood of normal children

ABSTRACT OF DISCUSSION

DR LEWIS HENRY KOPLIK, New York. A feature of great interest in this paper is the demonstration in the child of antibodies of protective or neutralizing character following the administration of the so called antigen. With the exception of the work of Miss Lucy Mishulow on the mouse protection test and the experiments of Dr Cohen and Dr Scadron, read here yesterday, using Miss Mishulow's criteria, the effectiveness of materials used in the prophylaxis of pertussis has been judged in general by their capacity to prevent or to mitigate an infection the result of a hypothetically sufficient exposure. It was, if I recall correctly the practice of Miss Mishulow, following her demonstration of the presence of a true toxin, through the Schwartzman phenomenon, to include some of the agar washings in the preparation of her vaccine. I also was able to demonstrate in Schwartzman's laboratory in 1934, in brain broth culture filtrates, a toxin of considerable potency judged by its capacity to produce the Schwartzman phenomenon. The filtrates were antigenic as evidenced by the precipitin titer developed in the serum of rabbits injected with them, but no neutralization tests were done at that time. It is important to know, and experiments should be done to demonstrate, what antitoxin titer, if any, is necessary to protect against the disease, and I think it should be emphasized that such antitoxin titer in man be developed if possible by active rather than passive immunization. One should not, I think, be led by Dr Bullova's figures on protection afforded by the administration of antitoxin to discard active for passive immunization, for it must be remembered that such immunity is transitory as well as sensitizing to the species of serum used. The use of antitoxic serums should, however, as the authors suggest, be helpful following exposure of sick or debilitated infants or in those who have not as yet had the opportunity to be immunized.

DR JESSE G M BULLOWA, New York. It is unfortunate that pertussis is sometimes regarded exclusively as a disease of the respiratory tract. Dr Dolgopel at Willard Parker Hospital found that, in the autopsies of 31 patients dead from pertussis, half of them showed an encephalopathy as well as pneumonia. There are many problems which require elucidation: the dose of both toxoid and antitoxin, the duration of passive immunity and also of active immunity. Recently we had a very definite demonstration concerning the value of prophylactic injection when 2 children were exposed to an older brother. One of them was slightly sensitive to rabbit serum. That was taken as an excuse for omitting the antitoxin. In a week this patient came down with pertussis. The other has remained well, having received prophylactic antitoxin.

PERSONALITY CHANGES AND BEHAVIOR DISORDERS OF CHILDREN FOLLOWING PERTUSSIS

A REPORT BASED ON THE STUDY OF FIVE HUNDRED PROBLEM CHILDREN

LOUIS A LURIE, MD
AND

SOL LEVY, MD
CINCINNATI

Many studies have been made of the cerebral changes in pertussis. These pathologic changes have been divided into three principal groups, namely (1) hemorrhagic, (2) degenerative and (3) inflammatory.

Mental abnormalities associated with many of these neuropathologic changes have also been reported.

In the present study, attention is directed to the personality changes and behavior disorders which may occur in children many years following an attack of whooping cough suffered early in infancy. A successive group of 500 problem children who had been studied intensively at the Child Guidance Home was selected and the incidence of whooping cough in the group was noted. This was found to be 48.6 per cent, or 243 cases. Of this number 58 children were 2 years of age or younger when the attack of whooping cough occurred, while 60 were 2 to 5 years of age and 41 were 5 years or older when the attack occurred. In the remaining 84 cases, the history was not specific regarding the age, the history merely stating that the attack occurred early in childhood.

This study concerns itself only with the group of 58 children who suffered from whooping cough at the age of 2 years or younger.

In 34, or 58.6 per cent of the 58 children composing this group there appeared to be a definite relationship between the neurologic sequelae of the whooping cough and the behavior disorders and personality changes shown by them later in life. In other words, it was felt that the antisocial, asocial or abnormal behavior or personality distortions which these children exhibited in later years had as their bases structural changes produced in the brain during the attack of whooping cough. This conclusion was reached only after a very careful and thorough study and evaluation of all the physical, social, emotional, intellectual, constitutional and hereditary factors that directly or indirectly might have had a bearing on the problems presented by this group of children.

There were 24 boys and 10 girls in this group. This ratio of boys to girls is approximately the same as the ratio of boys to girls in the total of admissions to the Child Guidance Home.

The age range of the children at the time of their referral for study was from 4 years 4 months to 17 years 4 months. The age range according to the time of the occurrence of the whooping cough was from 3 weeks to 2 years.

Twenty-one of the children were referred for general behavior problems ranging from incorrigibility and delinquency to various forms of psychopathic behavior. Eight children were referred because of school maladjustment and 5 because of 'general nervousness.'

From the Child Guidance Home of the Jewish Hospital.
Read before the Section on Nervous and Mental Diseases at the
Ninety Third Annual Session of the American Medical Association
Atlantic City N. J. June 10 1942

The histories in all the cases showed that the children had not suffered previous to the attack of whooping cough from any other inflammatory or infectious diseases or from prenatal, natal or postnatal cerebral trauma. Furthermore, although in some of these cases there was a history of acute infectious or inflammatory diseases or injuries to the brain subsequent to the attack of whooping cough, the onset of the problem antedated these later diseases or injuries. In addition, the developmental histories of the children in many cases indicated clearly the sequential relationship between the attack of whooping cough and the retardation in their physical and mental growth as shown in the delay in the time of onset of walking and talking.

Sixteen of the children gave a history of delay in the onset of walking and talking, following the attack of whooping cough. In 2 of the children who had walked and talked before the attack of whooping cough, walking and talking were arrested immediately after the attack. Considerable time elapsed before they again walked and talked. Nine children had associated convulsive seizures. In 1 the seizures still occur.

The pertinent physical, neurologic, psychological and psychiatric findings were as follows:

The general physical findings were essentially negative in every case. The blood Wassermann and Kahn reactions were also negative in all cases. With the exception of 1 case, the same was true for the tuberculin reactions. All the other laboratory findings were within normal limits.

Nine of the group showed various forms of endocrine disturbances.

The neurologic findings were both numerous and significant. They were present in 25 cases of the series. Thirteen showed pyramidal signs, 2 showed extrapyramidal and 10 showed combined signs.

Nerve deafness was an unusually frequent symptom, occurring in 15 children. Nine children manifested various forms of speech disturbances.

Electroencephalographic tracings were made in 6 cases, and in 5 of these the tracings were definitely abnormal. The diagnosis on the bases of the tracings was epilepsy 2, cerebral dysrhythmia of a generalized nature 2 and cortical deterioration 1.

The results of the psychometric tests were as follows. Two children had superior intelligence, 8 had average intelligence, 9 had subnormal intelligence, 5 had borderline intelligence and 10 were definitely feeble-minded.

From the standpoint of behavior, the children were divided into four groups. The children in the first group showed types of behavior that were classifiable as prepsychotic and psychotic. They tended to withdraw from the group, were given to day dreaming and fantasizing and were not interested in their personal appearance. A tendency to flight from reality was apparent. Emotional poverty was an outstanding symptom. Many also evidenced paranoid ideas and visual and auditory hallucinations. Eight children were placed in this group. The following case report is an example of this group.

M E, a white girl aged 14, was referred because she presented a severe behavior problem both at home and in school. Lately she had had terrific outbursts of rage, during one of which she attempted to choke her mother and her aunt. According to the history, the girl had had severe temper outbursts since the age of 4 years. Very often she would beat her head against the wall or floor if frustrated. She had always been

cruel to children and especially to animals. She was an inveterate liar. Her school work was very poor. She truanted frequently and could not get along with the teachers. According to the medical history, birth and delivery were normal. Walking started at the normal time. The girl, however, did not begin to talk until she was 4 years old. At the age of 20 months she had had a severe attack of whooping cough. There were no other childhood diseases or injuries. The medicosocial family history was not germane to the problems presented by the child.

The physical examination was essentially negative except for a systolic murmur at the apex. The girl had a 28 per cent hearing loss in the right ear and a 24 per cent hearing loss in the left ear. There were no other abnormal neurologic findings, and all the laboratory tests were negative. The endocrine status was that of hypergonadism. On the psychometric test the girl made an intelligence quotient of 70 per cent and on the social maturity test she scored 99.2 per cent.

Her behavior at the Child Guidance Home was very significant. She kept aloof from the other children and made no effort to mix with them. She was not interested in her personal appearance. She appeared to be day dreaming all the time. The girl was very suspicious and felt that every one was talking about her. She had no special interests. There were many displays of temper, especially when she was thwarted. The girl expressed many paranoid ideas, and there were evidences of auditory and visual hallucinations. She told that she heard voices which commanded her to kill. She always heard these voices when she was in bed. In her visual hallucinations she saw a small, dark woman standing in front of her also ordering her to kill. During one of her temper outbursts the girl attacked one of the workers and tried to kill her. Her conduct during the temper outbursts was extremely violent.

The second group, which consisted of 6 children, manifested progressive intellectual deterioration. However, their reactions were not merely those of feeble-minded children. Their ability to achieve was even lower than their intellectual capacities. As a group they were fairly tractable. However, because of the progressiveness of the deteriorative mental process their helplessness in meeting ordinary life situations became more and more outstanding. As an example of this group the following case is cited.

M C, a white girl aged 17 years, was referred because she was unable to carry out simple directions and required a great deal of supervision.

Birth and delivery were normal. The girl was in perfect health until the age of 5 months when she had a very severe attack of whooping cough. Following this illness she did not progress normally. She first began to walk and to talk when she was 2½ years old. The only other childhood diseases were measles and mumps which occurred at the ages of 5 and 9 years respectively. Both of these illnesses were said to have been very mild.

The medicosocial family history was negative as far as the problems presented by the patient were concerned.

The general physical examination was negative except for 34.6 per cent hearing loss in the right ear and 13.3 per cent hearing loss in the left ear. There was no endocrinopathy, and all the laboratory tests were negative. The neurologic examination was also negative and the electroencephalographic tracings were normal. The girl's intelligence quotient was 64 per cent. In the past ten years it had dropped from 97 per cent to 64 per cent. On the Vineland social maturity test the girl received a social quotient of 66.6 per cent.

The girl appeared happy at the Child Guidance Home and was fairly easily managed. She seemed to be unusually interested in boys and on several occasions exposed herself. She was slovenly about herself and was untidy in the dormitory. All her reactions were extremely immature and characteristic of those of an intellectually retarded girl. Her memory for both recent and past events was poor and she was unable to

carry out simple directions. She needed constant supervision. At times her behavior was erratic, especially when she was thwarted in any way.

The third group was the largest in that it contained 17 children. The behavior of this group was of the type that is usually described as postencephalitic. The conduct and personality changes form a typical picture which is easily recognized even in the absence of positive neurologic findings. The behavior of the children was characterized by hyperactivity, extreme restlessness, destructiveness and short attention span. Inhibitions and fear of consequences appeared to be lacking. Their conduct was both impulsive and unpredictable. They were capable of experiencing remorse but this did not seem to prevent them from repeating their destructive acts. It is interesting to note that in many instances the intellect was not involved. The following case is typical of this group.

J. L., a white boy aged 6 years, was referred because he was nervous, restless and disobedient in school. This behavior was noted when he was first enrolled in school. His academic achievement was far below his intellectual capacity. He did not mix with other children and was not liked by them. He had never gotten along well with other children, for he tended to hit them without provocation and for this reason was threatened with exclusion from school.

His birth and delivery were normal. Except for a severe case of whooping cough at the age of 5 months, the boy had never been seriously ill. His developmental history was normal.

The medicosocial family history was entirely negative as far as the boy's problems were concerned.

The general physical examination also was entirely negative. The boy had a hearing loss of 21.3 per cent in the right ear and of 18.6 per cent in the left ear. The visual examination showed a high degree of hypermetropia. The neurologic examination revealed a slight speech defect, hyperactive tendon reflexes and a positive Babinski reflex on the right. The endocrine examination as well as the laboratory tests were negative. The electroencephalographic tracing was definitely abnormal, showing a diffuse cerebral dysrhythmia without localization. On the psychometric test the boy secured an intelligence quotient of 101 per cent, classifying him among children of good average intelligence. On the social maturity test he scored a social quotient of 94 per cent.

On his arrival at the Child Guidance Home, the boy showed no fear or embarrassment. He possessed an unusual amount of fearlessness for a child of his age but was extremely restless and hyperactive. His attention span was very short. He was not able to concentrate on any one task for any length of time. He was demanding and aggressive and constantly annoyed the other children. He was extremely noisy, yelling all the time, and very often he was observed spitting continuously. He was very cruel to the younger children, and at times he even attacked older children without any apparent provocation. His conduct was unpredictable. He had severe temper tantrums, and at such times he tried to strike every one near him and was very destructive. At such times also it was impossible to reason with him. At other times, however, he was very tractable and polite and did willingly what he was told. He made friends with the other children very easily, but after playing with them nicely for a while would suddenly slap them without any provocation whatever.

The fourth group, in which there were 3 children, showed a combination of two or more of the aforementioned types of behavior. This is illustrated in the following case.

V. H., a white girl aged 4½ years, was referred because she did not talk, had many temper tantrums and seemed physically and mentally retarded. The temper tantrums started at the age of 3 years and had gradually increased in frequency and severity. The girl had never been able to compete with other children her age either mentally or physically.

She was born to a primipara, birth and delivery being normal. Dentition began at the normal age. At 1 year of age she had a very severe attack of whooping cough, following which her development was definitely delayed. She did not start to walk until almost 2 years and up to the present has not talked.

The medicosocial family history was entirely negative as far as the problems presented by the child were concerned.

Except for some general physical underdevelopment, the physical examination was also negative. The laboratory findings were normal. The neurologic examination revealed decidedly diminished patellar reflexes and a positive Babinski sign on the left. On the psychometric examination the girl made a mental age between 1½ and 2 years, thus giving her an intelligence quotient of 45 to 50 per cent and classifying her as definitely feebleminded. The girl's social quotient was 46.9 per cent.

While at the Child Guidance Home, her behavior was very immature. She was dependent in everything. Her table manners were poor. She took great delight in squashing the food through her fingers and breaking the bread into small pieces and throwing them on the floor. She used her hands to convey the food to her mouth even though she was well able to use the fork. She was obstinate and stubborn and any thwarting was met with a severe temper tantrum on her part. She was exceedingly restless, had a short attention span and was not able to occupy herself constructively. She was intellectually retarded and was unable to carry out simple commands. The girl did not talk at all but constantly made gurgling sounds. She slept well but suffered from nocturnal enuresis. Soiling occurred every day.

COMMENT

Whooping cough when occurring early in infancy may have serious consequences, as it may prevent the normal intellectual and personality development of the child. This statement is based on the results of the present study in which 34, or 58.6 per cent, of a group of 58 children who had had whooping cough before the age of 2 years (68 per cent of an unselected group of 500 problem children) showed definite behavioral, intellectual and personality changes later in life, apparently as a result of the neuropathologic sequelae of whooping cough.

At this point it should be noted again that in this series of cases all other possible exciting or contributory factors, such as hereditary influences, birth trauma, other acute diseases or injuries and psychologic and environmental factors have been ruled out as major factors.

Twenty-four of these children were boys and 10 were girls. This ratio of boys to girls is the same as the ratio of the general admissions to the Child Guidance Home. From this it would appear that sex is no factor in this connection.

In the majority of cases the attack of whooping cough occurred between the third and the seventh month of life, although the majority of the children were first referred for study between the ages of 10 and 11 years. In some of the cases there was even a longer interval between the age when the attack of whooping cough occurred and the age when the problem first became noticeable or pressing. The insidiousness of the progression of the disastrous psychopathologic effects of whooping cough thus becomes apparent. This also points to the need for a careful medical history when studying behavior disorders of children. Many obscure cases of behavior disorders may become understandable if evaluated in the light of the history of an attack of whooping cough early in infancy.

The types of behavior problems presented by these children were not characteristic. They did not differ from the general run of problems presented by children

studied at Behavior Clinics. The majority of the children (21) were referred because of general behavior problems ranging from incorrigibility to psychopathic types of behavior, 8 were referred because of school maladjustment and 5 for various physical or nervous disorders.

The general physical findings were not significant. The results of the laboratory examinations were significant only from the standpoint of the negative findings.

Nine of the children showed various forms of endocrine involvement. This, however, is not particularly significant, as this percentage is in accord with the percentage of endocrinopathies occurring among all the children studied at the Child Guidance Home.

A striking and characteristic finding in many of the cases was the history of delay in the time of onset of walking and talking. Sixteen of the children were pronouncedly delayed in these respects. Two children following the attack of whooping cough stopped walking and talking, whereas previously they had walked and talked. In 9 cases there were associated convulsions. Only 1 child still had convulsions at the time of this study. These facts would tend to point to definite organic changes in the brain produced during the course of the disease.

Further proof of the pathologic involvement of the nervous system was shown by the large number of cases (25) in which positive neurologic findings were still present. These consisted of both pyramidal and extrapyramidal lesions.

Of 6 cases in which electroencephalographic tracings were made, 5 were definitely abnormal. Of these, 2 could be classified as epilepsy, 2 as general cerebral dysrhythmia and 1 as cortical deterioration. This is too small a number to permit of any generalization, however, the fact that in 5 cases the electroencephalograms showed abnormal tracings appears to indicate that irreparable brain damage may occur during the course of the disease.

Additional proof for this assumption is furnished by the findings of Evans and Maltby.¹ They studied the pneumoencephalograms of 6 children who presented either behavior disorders or neurologic sequelae due to whooping cough suffered in early infancy. All the pneumoencephalograms showed definite cerebral changes, principally in the form of cortical atrophy.

The frequent occurrence of nerve deafness and various forms of speech disturbances is especially worthy of mention. Fifteen children suffered from nerve deafness, while 9 manifested some form of speech defect. The implication of this in connection with problems of school maladjustment are very obvious.

The psychologic and psychiatric findings were extremely significant. On the Stanford revision of the Binet test, 24 of the children rated below average in intelligence. Of this number 9 had subnormal intelligence, 5 had borderline intelligence and 10 were definitely feeble-minded. The incidence of mental deficiency in this series of cases was much larger than in the entire group of children studied at the Child Guidance Home. This again points to possible cerebral injury.

All the children showed various forms of psychopathic types of behavior, which were divided into four distinct categories. The first group of children showed types of behavior which were classifiable either as prepsychotic or definitely psychotic. Eight children were so classi-

fied. Paranoid ideas, visual and auditory hallucinations and a tendency to withdraw from reality were among the outstanding characteristic symptoms exhibited by this group.

In the second group were placed those children (6) who showed progressive intellectual deterioration. These children for the most part were very tractable, but because of the progressive nature of the mental retardation they were unable to make normal adjustments to their life situations.

The third and largest group was composed of seventeen children who exhibited the typical postencephalitic type of behavior. The outstanding behavioral characteristics of this group were extreme motor restlessness, impulsiveness with a tendency to destructive activity and unpredictable behavior. Characteristically, very few of these children showed any intellectual retardation. As aptly expressed by Kahn and Cohen,² this condition appears to be "an organic drivenness of brain stem origin."

The fourth group consisted of 3 children who showed a type of behavior that was a combination of two or more of the foregoing types.

The manner in which whooping cough may produce such psychic and behavioral changes may be inferred from the results of neuropathologic studies of the brains of infants dying from whooping cough.

As early as 1842, neurologic complications in pertussis were noted and reported. However, it was not until 1899 that the results of the first autopsies of children dying from whooping cough and its complications were reported. West³ and Luce⁴ were the first to demonstrate minute hemorrhages, edema and cellular degeneration of the brain in their cases, and this hemorrhagic basis for the neurologic complications of pertussis was generally accepted for many years. In 1924 Husler and Spatz⁵ demonstrated irreversible degenerative changes of the cortex, dentate nucleus and corpus striatum without hemorrhage in 2 patients dying of whooping cough complicated by convulsions. They described a typical regressive change in the nerve cells of the cortex, with loss of staining properties in all structures of the cell except the nucleus. This study aroused considerable interest, as it provided the first definite evidence against a hemorrhagic basis as the sole cause for the neurologic complications of pertussis and suggested an encephalitic foundation for their occurrence. Jochims⁶ in 1928 confirmed the Husler and Spatz findings in a case at autopsy, however, he suggested the term "whooping cough encephalopathy." In 1930 Hiller and Grinker⁷ made a comprehensive study of the cerebral complications of whooping cough and attempted to explain the occurrence of these complications by applying the theory of "stasis and prestasis." According to these authors "there is apparently a gradual transition from a repairable disturbance of brain function on a functional circulatory basis (the explanation of certain transient nervous symptoms) to permanent defects." Chornyak⁸ stresses the role of

anoxemia occurring during the course of pertussis and other acute infectious diseases of childhood in the production of structural changes in the brain. Dolgopol,⁹ in a recent article, after reviewing the entire literature and reporting her own experiences, states that "the changes in the brain in pertussis are apparently noninfectious. They are most likely of circulatory origin and consist of edema, ischemic cellular degeneration, multiple hemorrhages (usually small) and lymphocytic plugs in veins and capillaries. On rare occasions a secondary encephalitic reaction⁷ may be observed in addition to the aforementioned changes." She concludes that the term "pertussis encephalopathy" proposed by Jochims "covers most adequately these conceptions and, in the present state of knowledge about the pathogenesis of lesions in the brain in pertussis, should be the term of choice for the cerebral complications in that disease."

Although from the clinical standpoint it was possible to divide the types of abnormal behavior exhibited by the children in this series into four principal groups, namely (1) prepsychotic and psychotic, (2) intellectual deterioration, (3) postencephalitic and (4) combined, no definite correlation could be made between a specific type of behavior and a specific type of brain involvement. In other words, with the possible exception of some of the postencephalitic cases it was impossible to tell from the clinical picture alone whether the types of behavior exhibited by the children were due to either circulatory, hemorrhagic or inflammatory changes in the brain as a result of the whooping cough.

CONCLUSIONS

From the data presented in this study the conclusion seems justifiable that whooping cough occurring early in infancy may lead to the development of severe behavior problems, intellectual deterioration, personality distortions and psychotic manifestations later in life. In all probability these psychopathologic conditions have as their basis structural changes in the brain produced during the attack of whooping cough.

ABSTRACT OF DISCUSSION

DR. A. R. VONDERAHE, Cincinnati: This report calls attention to the probable serious consequences of whooping cough in children under the age of 2. The personality changes and behavior disorders noted in some of these children calls for a thorough study of the underlying pathologic alterations and suggests that even in adult life a complete anatomic analysis of the central nervous system may very well show changes. With psychotic and psychopathic persons in adult life we tend to forget such things as whooping cough in infancy. In making a survey of the literature on pathologic involvements of the hypothalamus, pathologic reports were found to be generally inadequate in stating the exact localizing anatomic diagnosis. However, several clinical cases of diabetes insipidus with alteration of gonads and emotional changes following whooping cough were encountered. Gayler reports a case of diabetes insipidus which was preceded by whooping cough, in this case infantilism also developed. In Turner's case there was diabetes insipidus plus adiposogenital dystrophy following whooping cough. Daneri reported a case of diabetes insipidus associated with drowsiness, depression, convulsions and psychic changes following whooping cough. These cases all suggest an involvement of the anterior part of the hypothalamus and of the descending pathways from this area to the pituitary gland. I should like to ask Dr. Lurie whether any of the case histories at the time of the whooping cough

indicated cerebral or perhaps even hypothalamic involvement, thus forecasting the future hazard of the child? It may be noted that multiple hemorrhages and ischemic cell changes as well as other circulatory difficulties constitute a feature of the pathologic alterations in whooping cough. In this connection it might be well to inquire how severely all these babies were, whether there was a great deal of vomiting, how well nutrition was maintained and whether or not some of the vascular changes may have been of the Wernicke type and traceable in part to nutritional deficiency, particularly vitamin B or calcium deficiency.

DR. CHARLES BRADLEY, East Providence, R. I.: At the Bradley Home in East Providence we have been going over our case records of problem children to correlate the incidence of asphyxiating disease in the first two years of life with specific behavior traits and electroencephalographic tracings. We have been impressed for some years with the importance of such asphyxiating illness in the early years of childhood, probably before 2 years. Dr. Lurie's series of electroencephalographs is very short and the incidence of abnormalities he reports is no higher than the incidence of electroencephalographic abnormalities in problem children reported in the literature. My work is in pediatrics, and those of us who take care of babies with whooping cough under 2 years are impressed by the seriousness of the disease at that age. I should like to know how the incidence of whooping cough in the first two years of life in this series compares with the incidence of whooping cough in the general population as gathered from the public health reports.

DR. LOUIS A. LURIE, Cincinnati: In answer to Dr. Vonderahe's question relative to whether in my knowledge case histories showed any cerebral injury, I cannot say because these children were referred to us many years after the attack of whooping cough and we have no reports from the physicians who attended the children at that time. Hence we do not know whether any neurologic examination was made at that time. I agree with Dr. Bradley that movement of the brain in infants may be a potent factor in the production of cerebral damage. I was interested in what Dr. Freeman had to say in his discussion of the previous paper, namely that the greater the destruction of the brain in shock therapy, the better the results. Here we see the reverse. Where there has been destructive action on the brain as a result of an infection, personality changes of an undesirable type may follow. When I said that all other factors had been ruled out as causative influences, I specifically stated that what I meant was that they had been ruled out as major causes. In studying behavior disorders and personality changes, we know that a multiplicity of factors are as a rule involved in every case. The relative importance of various factors, however, is not the same. We can easily differentiate between major and minor factor, especially where we are sure as in the cases reported in this paper, what produced the cerebral disorder. Because of the large number of variables it was impossible to compare the incidence of whooping cough in our series with that in the population at large.

The Danger in the Use of the Tourniquet—The lesson the war taught us about the arrest of hemorrhage when met with in a case of compound fracture or occurring independently of that injury undoubtedly was the danger attending the use of the tourniquet. To allow a patient to whose limb a tourniquet has been applied to pass out of your sight, or worse still from under your care, came to be looked on as professional disgrace. The advice we gave to the regimental medical officer dealing with a case of severe bleeding from a recent wound and to the field ambulance officer doing duty in a crowded regimental aid post was, in all cases where bleeding would not cease from a natural arrest, or could not be controlled by the local pressure of a shell dressing to grasp the bleeding points with pressure forceps and send the patient down with these hemostats attached to his wound.—Wade Henry, *Emergency Surgery in the Field from War and the Doctor*, edited by J. M. Mackinnon, M.D., Baltimore: William Wood & Co., 1942.

POSTOPERATIVE ATELECTASIS

CLINICAL ASPECTS AND A REVIEW OF CASES

HERBERT W SCHMIDT, M.D.

LLOYD H MOUSEL, M.D.

AND

STUART W HARRINGTON, M.D.

ROCHESTER, MINN.

The surgical importance of atelectasis is obvious, it may complicate convalescence from any operation and it is the most commonly encountered pulmonary complication after abdominal operations. Interest in atelectasis is not new. Knowledge of postoperative atelectasis, however, has been acquired in comparatively recent years.

SOME NOTEWORTHY CONTRIBUTIONS

As long ago as 1850 Gairdner¹ presented the belief that atelectasis could be produced by obstructing a major bronchus with thick, viscid mucus. William Pasteur² in 1910 recognized and described the clinical features of this condition. Lee and Tucker³ in 1925 were first to demonstrate by bronchoscopy the mechanism of postoperative atelectasis. The cause of atelectasis in his case was found to be complete obstruction of the bronchi of the atelectatic lung with thick, tenacious secretion. Lemon⁴ in 1926, working with dogs, showed that secretion in the mouth was readily aspirated into the tracheobronchial tree in the course of general anesthesia. The position of the animal when anesthetized had an effect on aspiration of the secretion. The risk of aspiration decreased when the head was lowered through a horizontal to a declined plane. It vanished when the full Trendelenburg position was reached.

CAUSES

It is not surprising to learn, then, that postoperative atelectasis almost always develops as a result of decreased pulmonary ventilation and inadequate endobronchial drainage. These might be called the immediate causative factors, which in turn depend on the following remote causes: (1) the effect of the anesthetic agent on the patient; (2) the position of the patient at the time of operation; and (3) the type of operation performed. The manner in which each of these factors operates in most instances to produce atelectasis can be seen in one or more of the first three illustrations.

The patient represented in figure 1 is assumed to be undergoing an operation on the upper part of the abdomen and to be under general anesthesia. The laryngeal and cough reflexes are abolished by the anesthesia, making it possible for infected secretions from the nasopharynx, mouth and hypopharynx to be aspirated into the tracheobronchial tree. With the patient recumbent the course of the trachea as it descends is somewhat posterior. The course of the right main bronchus and of the bronchus to the lower

lobe of the right lung is more direct than that of the corresponding bronchi on the left side. Thus the infected secretions usually gravitate to the right side. The effectiveness of bronchial ciliary action is reduced by the overwhelming effect of the mass of secretion. The abdominal incision reduces vital capacity and the effectiveness of cough by weakening the abdominal muscles which take an important part in normal respiration and coughing. During this type of operation, retraction is made upward, to the right and to the left, to secure adequate exposure. Some of this force is transmitted to the under surface of the liver, which compresses the diaphragm and the lower lobes of the lungs. The effect is usually greatest on the lower lobe of the right lung. The splinting of the diaphragm and the compression of the lower lobes cause decreased ventilation. The result is a decrease in normal bronchial respiratory movements and impairment of endobronchial drainage. Thus there is a tendency for abnormal secretions to stagnate in the tracheobronchial tree. If these are not removed atelectasis may occur.

Figure 3 represents some of the conditions present during spinal anesthesia. The effects of making an abdominal incision and of retraction during operation, not shown in figure 3 are the same as those represented in figure 1. Spinal anesthesia, given for upper abdominal or renal operations, may cause motor paralysis up to the fourth thoracic segment. The resulting paralysis of the lower intercostal muscles causes reduced pulmonary ventilation, which favors stagnation of bronchial secretions. Atelectasis may follow.

The abnormal forces that are present during certain operations on a kidney or on a lung are represented in figure 2. Here the patient lies on the side opposite to the site of operation. The lower side is splinted by the weight of the body. Secretions gravitate into the lower lung. These last two factors favor the development of atelectasis in this lung.

PREVENTION

Prevention of atelectasis is of primary importance. In a recent article by one of us⁵ the following sentences appeared:

In cases in which suppurative disease of the lung is secondary to a malignant lesion obstructing the bronchus it is advisable to perform bronchoscopic aspiration of the lung at least once and, if necessary, several times before operation, to free the lung of as much of the infected secretions as possible. As I have said previously, in some instances the general condition of the patient is markedly improved after removal of the toxic secretions so that a patient who may have been believed clinically to have an inoperable lesion will improve sufficiently to withstand surgical treatment. In cases in which an extensive suppurative disease is associated I believe that it is advisable to aspirate the secretions by the use of a bronchoscope after the patient has been anesthetized on the operating table but before the operation is started. This will prevent the secretions from going into the opposite lung when the diseased lung is manipulated at the time of operation.

An attempt should be made to avoid prolonged anesthesia because the longer anesthesia lasts the more opportunity there is for secretion to collect. During general anesthesia the nose, mouth and hypopharynx should be kept free from excessive secretion by aspiration through a catheter. Intratracheal methods of anesthesia tend to prevent aspiration of secretions. If a Magill tube of large size is inserted under direct vision before operation, the rima of the glottis can be fitted

snugly.⁶ If the type of operation will permit, the Trendelenburg position should be used, since this will allow secretions to gravitate to the mouth, where they can be easily removed. The head of the operating table should be inclined 10 degrees or more to overcome the normal posterior slope of the trachea⁷ as it descends. In the

Fig 1—Some features of general anesthesia and of operation on the upper part of the abdomen which tend toward production of postoperative atelectasis

course of the operation abnormal amounts of secretion in the tracheobronchial tree should be removed promptly by bronchial catheter or bronchoscopic aspiration.

It is our practice to give the benefit of certain precautionary measures to all patients who have undergone lobectomy or pneumonectomy as soon as the operation has been completed. The incidence of pulmonary collapse in this group has been extremely low.

To quote again from the paper on pneumonectomy:⁸

Preventive supportive measures should be taken immediately after the operation before the patient leaves the operating table. I believe it is advisable to perform bronchoscopic aspiration of the remaining lung in all cases while the patient is still anesthetized. It is an essential procedure in those cases in which there has been an excessive amount of mucus or suppurative disease of the affected lung. In all cases a roentgeno-

Fig 2—The position of the patient in some operations tends to cause postoperative atelectasis

gram should be taken while the patient is on the operating table and immediately after the wound is closed, and it should be developed and examined immediately. If there is any evidence of atelectasis in the remaining lung, bronchoscopic aspiration of the lung is performed on the operating table. Following

this aspiration, another roentgenogram is made immediately and examined. If the condition is improved, the patient is removed from the operating room. If it is not, bronchoscopic aspirations are performed until the air passages are entirely free of secretions. It is most essential not to remove the patient from the operating room until the air passage of the remaining lung is entirely clear. In some instances it may be advisable to keep the patient in the operating room until he has fully recovered from the anesthetic and until the cough reflex is reestablished.

After the patient has returned to his room, he should be turned frequently and instructed how to perform deep breathing exercises at regular intervals. Hyperventilation with a mixture of 5 per cent carbon dioxide and 95 per cent oxygen is a valuable method of stimulating deep breathing. It should be given at regular intervals in the immediate postoperative stage by one who is experienced in its use.

Fig 3—Some effects of spinal anesthesia which favor postoperative atelectasis

In the same stage, and throughout convalescence, abdominal binders should be kept below the level of the thorax. If they are applied too high they will restrict the respiratory excursions of the thoracic wall. If abnormal amounts of tracheobronchial secretion accumulate they should be coughed up. Nurses should be instructed in how to support the abdominal wall of the patient during coughing. This support lessens the pain and increases the effectiveness of coughing. Although narcotics are necessary in the postoperative period for relief of pain, excessive amounts should be avoided, since the drugs depress the respiratory center and the cough reflex.

Elective surgery should not be done in the course of, or soon after, an acute infection of the respiratory tract, since the danger of postoperative pneumonia is increased under such conditions. A period of at least ten to fourteen days, free of symptoms, should elapse following an acute infection of the respiratory tract before any elective operation is done. At times it is not possible to avoid operating on a patient who has

6 Lundy J S, Tuohy E B, Adams R C, Mousel L H, and Seldon T H. Annual Report for 1941 of the Section on Anesthesia Including Data on Blood Transfusion. Proc Staff Meet Mayo Clin 17: 225-238 (April 15) 1942.

7 Haight Cameron and Ransom H K. Observations on the Prevention and Treatment of Postoperative Atelectasis and Bronchopneumonia. Ann Surg 114: 243-262 (Aug) 1941.

an infection of such nature and, under these conditions, extremely close observation is necessary. The same is true for any patient who gives a history of other evidence of a chronic infection of the bronchial or pulmonary system, such as bronchitis, asthmatic bronchitis or bronchiectasis. In the presence of the last named condition elective operation should be postponed until the best possible bronchial drainage has been

established by postural methods combined with bronchoscopic aspiration. Patients who have bronchiectasis should be subjected to bronchoscopy immediately after operation.

TREATMENT

In most instances, atelectasis can be successfully treated by hyperventilation with carbon dioxide and oxygen and by performing deep breathing exercises

Fig 4—Atelectasis of the left lung occurred after appendectomy for acute gangrenous appendicitis. Bronchoscopy revealed 50 cc of mucopus in the left main bronchus; this was aspirated. Recovery was prompt. The roentgenogram on the left was taken just before bronchoscopy; that on the right was taken immediately after bronchoscopy. There already is evidence of reexpansion of the involved lung. As shown in the chart the temperature, pulse and respirations promptly reached normal.

Fig 5—Forty-eight hours after a right pelvolithotomy was performed for renal stone, atelectasis of the left lung was recognized. Bronchoscopy revealed that the left main bronchus was filled with mucopus. About 60 cc of this material was aspirated and sulfathiazole was given. The roentgenogram on the left was taken just before bronchoscopy; that on the right was taken seventy-two hours later and gives evidence of some residual infiltration in the left lung. As shown in the chart the temperature, pulse and respirations responded to treatment.

Fig 6—The patient represented here had severe hypertension. Three years before he came to the clinic he had a cerebrovascular accident with resulting right hemiplegia. Examination revealed residual right hemiparesis. Left hydronephrosis also was found and left nephrectomy was performed. Atelectasis developed in the right lung. On aspiration of the right lung by means of a bronchial catheter a large amount of blood-tinged mucopus was obtained. The results of treatment were excellent. The roentgenogram on the left was taken before aspiration and that on the right after aspiration. The chart makes evident the effect of treatment on the temperature, pulse and respirations.

Abnormal amounts of bronchial secretion should be raised by coughing. If prompt relief of the complication is not obtained by these methods, bronchial catheterization or bronchoscopic aspiration should be done. The latter procedure is preferable because it is done under direct vision.

TABLE 1—*Pulmonary Involvement*

Degree of Involvement	Right Lower Lobe	Right Middle Lobe	Right Upper Lobe	Right Lower and Middle Lobes	Entire Right Lung	Left Lower Lobe	Left Upper Lobe	Entire Left Lung	Right Lower and Middle Lobes
Minimal localized infiltration	8	0	0	0	0	2	0	0	0
Partial collapse	12	0	0	0	0	2	0	0	0
Complete collapse	1	0	0	0	0	0	1	0	0
Pneumonia secondary to atelectasis	14	0	1	1	1	3	0	1	0
Total	35	0	1	1	0	7	1	11	11

The earlier atelectasis is recognized and proper treatment instituted, the less danger there is of secondary pneumonia developing. In most cases postoperative pneumonia arises secondary to atelectasis. If pneumonia develops chemotherapy should be given and the drugs of choice at the present time are sulfathiazole and sulfadiazine. If postoperative atelectasis goes unrecognized for a long period, pulmonary abscess may develop.

The results of early treatment of postoperative atelectasis are excellent. The temperature, pulse rate and respiratory rate drop rapidly to normal levels as soon as adequate endobronchial drainage has been established (figs. 4 and 5).

REVIEW OF CASES

In selecting for study cases of atelectasis encountered at the Mayo Clinic in 1941, certain criteria were adopted. For instance, routine postoperative physical examination of many patients who have undergone operation on the upper part of the abdomen will elicit evidence of decreased ventilation of the right lower lobe and of elevation of the right side of the diaphragm. These changes at times will persist for four or five days although the patient is making what is considered a normal postoperative recovery. This type of case is not included in the series under discussion. Moreover, cases in which the lungs were roentgenologically negative were excluded.

There remained 84 cases of partial or complete atelectasis. This group included cases in which, first, the roentgenologic findings were positive. The incidence of positive findings undoubtedly would have been higher if in every surgical case postoperative thoracic roentgenograms had been made. As the study actually was conducted, roentgenograms usually were made as soon as the presence of a complication was suspected. Roentgenologic evidence of such complication ranged from that characteristic of massive collapse to that expressive of minimal infiltration demonstrable in one or both lower lobes, provided the minimal infiltration was thought to represent focal atelectasis. There was also another provision. The clinical picture had to support the roentgenologic impression.

This clinical picture consisted of restricted movement on the involved side, at least this sign usually was seen. Impairment to percussion and decreased breath sounds over the involved lung usually were found.

The diaphragm was elevated and the mediastinum was

shifted toward the involved side. After the bronchial secretion had been removed by cough or bronchoscopic aspiration and the atelectatic lung was expanding, it was not uncommon to elicit bronchial breathing in spite of the fact that the temperature, pulse and respiratory rate had become normal.

In table 1 is recorded the situation and degree of pulmonary involvement.

Fifty-eight of the patients (69 per cent) were men and 26 (31 per cent) were women. The usual explanation for the high incidence among men is that men are predominantly diaphragmatic and abdominal breathers and their vital capacity is more sharply reduced after abdominal operations than is that of women, who are predominantly costal breathers.

The average age of the men in the group was 50 years, their average weight was 158 pounds (72 Kg) and their average height 68 inches (203 cm). The average age of the women was 50 years, their average weight was 148 pounds (67 Kg) and their average height 63 inches (190 cm).

A review of the routinely made preoperative roentgenograms of the thorax failed to reveal any significant consistent findings which might have been used to foretell the development of atelectasis. Certain complicating conditions were present in some cases. One patient, whose operation was for ruptured ectopic pregnancy, had an acute cold at the time of operation. Four patients gave the history of having had a recent cold, 12 had a chronic cough, 4 had asthmatic bronchitis, 3 had emphysema, 1 had bronchiectasis, 1 gave a history of coronary thrombosis, 1 had hemiplegia, 1 had cardiac decompensation, 1 had coronary sclerosis with a left bundle branch block and 2 had diabetes mellitus.

The incidence after different types of surgical operation was as follows: biliary operations 31 cases (36.9 per cent), gastric operations 18 cases (21.4 per cent), operations on the colon 9 cases (10.7 per cent), operations on the kidney 8 cases (9.5 per cent), repair of inguinal and femoral hernia 6 cases (7.1 per cent),

TABLE 2—*Operations Performed with Patients Lying on the Side*

Diagnosis	Operation Performed	Type of Anesthesia Used	Site of Atelectasis
Right renal calculus	Right nephrolithotomy	Spinal	Entire left lung
Tuberculosis of right kidney	Right nephrectomy	Spinal	Entire left lung
Hypertrophy of right kidney	Right nephrectomy	Ethylene and ether	Entire left lung
Acute right hydronephrosis	Right nephrectomy	Nitrous oxide and ether	Left lower lobe
Left pyonephrosis	Left nephrectomy	Spinal	Right lower lobe
Left hydro-nephrosis	Left nephrectomy	Nitrous oxide and ether	Entire right lung
Left hydro-nephrosis	Plastic operation on left kidney and left nephrectomy	Spinal, nitrous oxide and pentothal sodium	Right lower and middle lobes
Right psoas abscess	Exploration of right perinephric region, drainage of right psoas abscess	Spinal	Entire left lung

a biliary and a gastric operation on the same patient 3 cases (3.6 per cent), operations on the pelvis 3 cases (3.6 per cent), appendectomy 2 cases (2.4 per cent), operations on the thyroid gland 2 cases (2.4 per cent), removal of a dermoid cyst of the mediastinum 1 case (1.2 per cent), left lower lobectomy 1 case (1.2 per cent).

In some of the cases clinical evidence of pneumonia developed secondary to atelectasis. All patients received chemotherapy in addition to the measures pre-

viously described to promote better pulmonary ventilation and bronchial drainage. The drugs usually given were sulfathiazole and sulfadiazine.

In all cases in which atelectasis followed operation on the kidney the lung affected was the one corresponding to the side on which the patient was lying and which was being splinted by the weight of the body during operation (table 2 and fig 6). The right lung, and particularly its lower lobe, was involved in the highest number of cases after operations on the upper part of the abdomen. The right lower lobe was involved alone in 45 per cent of all cases.

The results of treatment in the entire group were good. All patients recovered. When treatment was started within forty-eight hours after onset of the complication the results were excellent. If the complication existed seventy-two hours or longer before treatment was begun, recovery was slower because usually by that time there was clinical evidence of secondary pneumonia.

SUMMARY

Atelectasis may complicate convalescence from any operation, it is the most commonly encountered pulmonary complication following abdominal operations. It almost always occurs as the result of decreased pulmonary ventilation and inadequate endobronchial drainage. The effects of the anesthetic agent on the patient, the position of the patient at the time of operation and the type of operation performed play important parts in the causation of this complication. Bronchoscopic aspiration is useful both in preventing and in treating postoperative atelectasis.

In a series of 84 selected cases of atelectasis, 58 of the patients were men and 26 were women. The average age of both men and women was 50 years. There were no preoperative roentgenographic signs by which likelihood of postoperative atelectasis could have been foretold. In 52 of the cases the operations were on the biliary tract or stomach, in 9 cases on the colon and in 8 cases on the kidney or its surrounding tissues, the number of cases representing other operations probably were not significant. In all cases in which atelectasis followed operation on the kidney, the lung affected was the one corresponding to the side on which the patient was lying. If treatment was started within forty-eight hours after the complication occurred results were excellent. If the complication existed for seventy-two hours or longer before treatment was begun, recovery usually was slower, since secondary pneumonia generally had developed.

ABSTRACT OF DISCUSSION

DR PHILIP D. WOODBRIDGE, Philadelphia. Dr Schmidt and his associates are to be congratulated on the absence of mortality in their series. There should be standing orders that, as soon as any rattling of fluid is heard in the respiratory tract, opiates and other respiratory depressants be omitted and that the patient be turned from side to side frequently. Whenever atelectasis is suspected, the patient should be turned with the affected lung uppermost and should be encouraged to cough. These conservative measures bring relief in the majority of cases. Suction should be used if relief does not follow quickly. If cyanosis, tachycardia or anxiety is present, no time should be lost with conservative measures but the bronchoscope should be used without delay. Carbon dioxide therapy is not universally accepted, and the question of its use is controversial. Recent work suggests that it may help to liquefy tenacious secretions. The administration of oxygen may appear necessary as a life saving measure in case of severe degrees of asphyxia, but its use might delay the clearing up of the atelectasis.

Getting the patient out of bed and forcing him to walk, if it is possible, might terminate some cases of atelectasis very quickly. There has been a tendency to glorify the bronchoscope in the treatment of postoperative atelectasis. Its frequent use for this purpose is not a true cause for pride but rather a matter to cause concern. Not only great length of anesthesia but also great depth favor the development of atelectasis. The anesthetist must avoid, eliminate or combat such contributory factors as traumatic concentrations of irritating vapors, obstruction in the respiratory tract and resistance in the gas machine and in the connecting tubes, and respiratory depression from narcotics, spinal anesthesia, tribromethanol or cyclopropane. In inhalation anesthesia with very quiet breathing it seems likely that constant slight positive pressure (1 or 2 mm of mercury) throughout all phases of the respiratory cycle may prevent gross atelectasis on the operating table. This effect is produced by the spirometer type of bag of the Connell machine and may be produced with other machines by putting a light weight on the ordinary breathing bag according to the method of Albert Miller. Some anesthetists believe that it is well to taper off high concentrations of oxygen in the respired mixture toward the end of operation, using an inert gas such as helium or nitrogen, so as to avoid leaving the alveoli filled with rapidly absorbable gases when the breathing suddenly becomes quiet after removal of the mask. Immediately after the prolonged administration of any inhalation anesthetic, suction should be used routinely in the pharynx, or, if an endotracheal tube is in place, suction should be used through this if the presence of gross amounts of secretion is suspected. Suction should also be used in the pharynx immediately before the removal and immediately after the removal of endotracheal tubes.

DR ALFRED HABEED, Fairfield, Ala. I should like to ask what the causes of atelectasis are in spinal anesthesia when the patient does not go to sleep. In a summary of cases made a year ago, I found that the percentage of atelectasis does not differ very much in local or spinal anesthesia from that of general anesthesia. When atelectasis does occur, however, it is, as the authors mentioned, usually in high abdominal cases and in patients who are old and weak and who usually have bad hearts—patients with only a fair prognosis. For this reason I should like to ask if the authors do not think that carbon dioxide is usually a little heavy stimulant for this type of patient. I do not employ bronchoscopy routinely. In fact, some writers believe that mucous plug is a far fetched theory. However, I do agree that mucous plugs occur in general anesthesia. We must bear in mind that heavy traction against the diaphragm during high abdominal surgery is a big factor in producing atelectasis. My treatment in the prevention of atelectasis is to cut down as much as possible on postoperative sedation and encourage exercise and deep breathing. I have had very few cases of atelectasis. I do not think any of these patients ever die from atelectasis. The patients are usually acutely ill for a couple of days, after which they recover.

DR LEO V. HAND, Boston. I should like to add a few words in agreement as to the causes and the importance of postoperative suction bronchoscopy as already expressed by the two previous speakers. In talking on postoperative suction bronchoscopy, there are lessons which I have learned from bitter experience which may be of value to the majority of anesthetists. My best results are obtained when the procedure is performed in the operating room. Many anesthetists have asked me "Do you do it in the room with the patient in bed?" It may be easily accomplished in the patient's room, but in the operating room one has a trained personnel and all the equipment necessary for any potential complication. As to the agent and method of anesthesia, I prefer to use cocaine as a topical anesthetic. In 1 instance, in the presence of postoperative thyroid crisis, pentothal was administered intravenously with a fatality, the only fatality. While setting up the postoperative suction bronchoscopy I employ a more conservative measure, such as the passing of a No. 20-24 urethral catheter into the trachea, frequently under direct vision. My experience of late has been that approximately 30 to 40 per cent of the patients

with this catheter method of aspiration will improve without the necessity for suction bronchoscopy. Again the question may arise as to the possible technical difficulties in the passing of the bronchoscope. My experience has been that it is much quicker and certainly easier for me to pass a bronchoscope through a laryngoscope than to attempt to pass it directly without laryngoscopy.

DR HERBERT W. SCHMIDT, Rochester, Minn. There are three points which I should like to emphasize. First, atelectasis is not an uncommon complication after general anesthesia. Second, postoperative bronchoscopic aspiration has a very definite advantage over the catheter method of aspiration of the tracheobronchial tree, since it is a procedure carried out under direct vision. At times, one of the larger bronchi will be found to be obstructed by a blood clot, and it will be necessary to remove this clot with forceps. If one used a catheter in a complication of this sort, it would be impossible to see what type of obstruction existed and very difficult to dislodge the foreign material. Third, atelectasis in itself may be accompanied by a very low rate of fatality but some of the conditions that it in turn produces such as pneumonia, abscess of the lung and empyema, will be associated with a fairly high fatality rate.

THE KENNY PRINCIPLES AND INJURIES OF THE KNEE JOINT

MAJOR VERNON L. HART

Medical Corps, Army of the United States

"Redevelop the quadriceps" is the first sentence in the chapter on Injuries of the Knee in Watson-Jones's recent textbook.¹ He also states that wasting of the quadriceps muscle is in itself a source of disability and that it occurs as a direct consequence of injury of the knee joint. An almost total reflex inhibition of the quadriceps may be observed, and the muscle is completely flaccid. It might well be paralyzed, for no flicker of active contraction seems possible. Wasting is unusually rapid and the volume of the muscle disappears far more rapidly than it can subsequently be regained. Treatment is therefore urgent. The inhibition must be overcome as soon as possible by the patient's own exercise. Massage and faradism are relatively useless, because the treatment is purely passive, it does not restore voluntary control, it encourages the patient in his apathy. It is not enough to advise the patient vaguely to practice exercise. Specific instruction is essential.

Watson-Jones also states that with quadriceps wasting the knee joint is imperfectly protected from the twists and strains of weight bearing. If muscle wasting is accompanied by rupture of ligaments, the disability is not relieved by operative construction of new ligaments or by the use of a knee cage because, if the muscle guard is lost, the ligaments stretch as soon as weight bearing is resumed and protection by a brace is inadequate and further wasting of muscles is encouraged. If the quadriceps muscle can be fully redeveloped, relaxation of ligaments and early osteoarthritis cause little or no incapacity. The joint is protected. The muscles are the first line of defense of the joint, the ligaments are the second.

The quadriceps and other muscles can be redeveloped and the morbidity resulting from injuries of bones and

joints can be greatly reduced if the Kenny principles, which have only recently been accepted by the medical profession in the treatment of anterior poliomyelitis, are applied in the treatment of injuries.

These principles are simple and scientific. They are the principles of mechanical and physiologic rest and are essential in any therapeutic program that deserves the name of functional treatment. They are not new principles but old ones which have been salvaged from a disorganized field of physical therapy and safely placed in the hands of the medical profession by a sincere, intelligent and practical nurse, Miss Elizabeth Kenny of Brisbane, Australia.

Quadriceps muscle insufficiency causing knee joint instability, adhesions of various gliding mechanisms including bursa, tendon sheaths, joints, intermuscular and fascial planes causing pain and loss of joint and muscle function, muscle spasm, and contractures of tendons, muscles, fasciae and ligaments causing deformity are familiar problems to all physicians who examine and treat traumatic conditions. They can be prevented by a clear understanding and proper application of the Kenny principles.

I was fortunate to have attended lectures, demonstrations and clinics which Miss Kenny gave at the University Hospital and General Hospital in Minneapolis from the fall of 1940 until the spring of 1942, when I entered the service of the U. S. Army, where I have had an unusual opportunity to apply the Kenny principles in the treatment of bone and joint injuries. I had practiced the principles of mechanical and physiologic rest and had taught that the integrity of the neuromuscular, circulatory and articular systems could be maintained in the presence of injury to bone, joint and soft tissues if mechanical and physiologic principles were adequately applied. I give credit to Miss Kenny for bringing order and respect to these principles and applying them in a functional system of treatment. She has given a great service to the bastard specialty of physical therapy, which many physicians have refused but must recognize as a legitimate and equal specialty of the medical profession.

I have selected the various internal derangement injuries of the knee joint for consideration in this paper, however any bone or joint injury could be presented to demonstrate the importance of the application of the Kenny principles. The program of treatment may also demand proper use of surgical principles of reduction and retention of a fracture, suture of a severed tendon, excision or suture of a fractured patella, excision of a torn and displaced semilunar cartilage, reduction of a dislocation, repair of a severed nerve, care of a burn, treatment of infection of a bone or joint, and aspiration of a hemarthrosis. The surgical principles are essential, but assiduous attention to the mechanical and physiologic or Kenny principles may determine the success or failure of treatment.

Miss Kenny has recognized a vicious clinical cycle in the acute stage of anterior poliomyelitis which frequently persists and causes deformity and disability. The sequence of pathologic events which she so keenly observed is muscle spasm, mental alienation of muscle and incoordination of muscle function. She has elaborated a system of treatment which relieves this triad and restores the functions of neuromuscular, circulatory

¹ Watson-Jones, Reginald. Fractures and Other Bone and Joint Injuries, ed. 2. Baltimore: William Wood & Co., 1941.

and articular units. The same triad of symptoms can be demonstrated following injuries and especially after internal derangements of the knee joint.

If any physician still doubts the actual existence of this syndrome or wishes to see each one of the three cardinal symptoms by clinical demonstration, I suggest the presentation of a patient with an acute internal derangement of the knee joint.

Following an injury to a knee joint one can demonstrate muscle spasm, mental alienation of muscle and incoordination of muscle function. These are the three cardinal attributes in the stages of poliomyelitis which Miss Kenny recognizes and treats, and she has demonstrated them to the satisfaction of the medical profession. If Sister Kenny was directed to examine and treat soldiers with internal derangements of the knee joint without the assistance of physicians, she would observe these three cardinal clinical findings as she did in her patients with poliomyelitis. She would treat what she found and the patients would recover with functional extremities because the integrity of the neuromuscular, vascular and gliding units would be preserved, deformity and disability would be prevented. Paralysis may be present in the patient with poliomyelitis and a torn semilunar cartilage may be present in the patient with a knee joint injury, but the syndrome of muscle spasm, mental alienation of muscle and incoordination of muscle function are the clinical features which exist in each. These three symptoms can be demonstrated, and they must be treated and relieved because they are the pathologic basis for deformity and disability. The torn cartilage or the ruptured ligaments may require subsequent surgical treatment, but the immediate therapeutic consideration is not surgical. A fractured patella or tibia may demand immediate surgical repair before the Kenny principles can be inaugurated. A fractured femur treated by skeletal traction is being neglected if mental alienation of muscle and incoordination of muscle function are not corrected during the weeks of skeletal traction. If the knee joint capsule is unduly tense because of hemarthrosis, aspiration may be required before the Kenny treatment can be efficacious.

Fig 1—Relief of spasm is the first consideration in treatment immediately following injury to the knee joint. This is accomplished with application of hot fomentations over the entire area of involved muscles and tendons. A large folded pillow is placed under the knee with patella and toes facing directly forward. The size of the pillow is gradually reduced as the muscle spasm and flexion deformity diminish.

Muscle spasm is present in the flexor muscles of the knee immediately following injury. The hamstring and gastrocnemius muscles and tendons are shortened because of the pain reflex spasm, and a flexion deformity of the knee joint is the result. A muscle in spasm is unable to relax and allow itself to lengthen. Any attempt actively or passively to lengthen the muscles

in contraction only aggravates the muscle spasm and increases the knee flexion deformity. The temporary contractures resulting from pain stimuli may become permanent contractures with a fixed flexion deformity of the knee if the condition remains untreated.

Relief of spasm is the first consideration in the treatment of the acute stage of internal derangement of the knee. Treatment is begun immediately. The patient

Fig 2—Muscle spasm, pain and flexion deformity have been relieved. Mental alienation of quadriceps muscle function is now demonstrable. Quadriceps function is restored by teaching the patient awareness of the muscle and of its normal action on the joint. Specific instruction is essential. A small infant pillow is placed under the knee to support the normal popliteal concavity. The upright board placed at the foot of the bed serves to stimulate the normal standing and postural reflexes.

is placed in bed on a firm mattress in the normal position of rest and the flexed knee supported by a fracture pillow, rolled towel or blanket (fig 1). An upright board placed at the foot of the bed serves to stimulate the normal standing and postural reflexes. The foot is not placed against the foot board during the period of active and painful muscle spasm. The Kenny treatment employs the use of moist heat. Wool flannel packs are immersed in boiling water, wrung twice through a tight wringer at the bedside and quickly applied over the entire area of involved muscles and tendons. The moist pack is covered with oiled silk and then with dry flannel. The pack is changed about every two hours and discontinued during the night. Burns do not occur if the packs are wrung quite dry. The relief of pain, muscle spasm and deformity is frequently dramatic. Aspiration of knee joint hemarthrosis is rarely necessary. A plaster of paris splint is not applied to the injured extremity.

The flexion deformity is the result of muscle spasm. Manipulation to reduce a suspected displaced semilunar cartilage is contraindicated. On numerous occasions I have observed at operation a torn cartilage displaced between the femoral condyles which had not prevented complete and active extension of the knee joint. Pain, muscle spasm and deformity are usually relieved after two to four days of treatment with hot packs and knee support. From the onset the patient is encouraged to keep the patella and toes facing the ceiling. In this position gravity seems to assist in the gradual correction of the flexion deformity of the knee as the muscle spasm subsides and the size of the pillow used for support is gradually reduced (fig 2).

Mental alienation can now be demonstrated. The quadriceps extensor femoris is the victim. As Pohl²

stated, spasm, besides the actual damage to the muscle tissue, has a further disturbing effect on the neuromuscular system. It must be kept in mind that motion of a joint in any given plane is a matter of control by opposing muscles. A muscle in spasm is a muscle attempting to contract. Spasm in the flexor will result in relaxation of the extensor of a joint. Furthermore, the extensor will refuse to pull against the flexor which is painful. The result is that the extensor ceases function, although it may be quite normal. Such a muscle appears to be paralyzed, whereas in reality it is only nonfunctioning. It has become divorced from the motor pattern.

Fig 3—The patient is not ready to become ambulatory. Muscle spasm pain and flexion deformity have been completely relieved but quadriceps muscle function has not been restored because the patient cannot extend actively and completely the knee against the resistance of gravity.

or alienated from the voluntary center regulating motion. It must be restored and it can be made to function by teaching the patient awareness of the muscle and of its normal action on the joint. This is first done by the process of stimulation, that is of exciting the proprioceptive nerve ending in the muscle and tendon which normally inform the central nervous system of the position and motion of the joint. Alternately lengthening and shortening a muscle within its normal range of contraction by moving the joint in a small arc will serve to do this, care being taken, however, not to stretch or stimulate the opposing muscle which is in spasm. This procedure may be repeated daily until such time as the spasm has been relieved in the opposing muscle by the use of the hot fomentations. The patient is then gradually retrained in the use of the alienated muscle, first being taught the position and action of the muscle but being allowed no weight bearing joint motion until proper function of the quadriceps muscle has been restored (fig 3). After normal rhythmic action of flexor and extensor muscles against the resistance of gravity is imprinted on the motor center, the patient is allowed to become ambulatory (fig 4).

Examination of the quadriceps muscle frequently reveals an almost total reflex inhibition. Not even a flicker of active contraction seems possible. I have seen this state of apparent paralysis of the quadriceps weeks and months after the original injury in patients who were never taught the program of muscle reeducation. Quadriceps atrophy and loss of active and complete knee joint extension may be associated with fixed contractures of the knee flexors and muscle incoordination. The normal function of the quadriceps which is active extension and stabilization of the extended knee is partially replaced by the force of gravity. The patient limps and guards the knee by using a cane or with his hand pressed against the front of the thigh to prevent the knee from sudden collapse while weight bearing. He may walk with the extremity externally

rotated so that the internal ligament of the knee checks the forward thrust at the knee level.

I teach the patient awareness by demonstrations of the anatomy and functions of his normal quadriceps first. The patient's interest and enthusiasm enhance restoration of the affected muscle, and after a few days of treatment by awareness of the affected muscle the muscle is no longer alienated from the motor center. Smooth motion and coordination are restored. The motor or neuromuscular physiologic unit is reestablished and bodily mechanics are preserved (fig 4).

Patients with the common types of internal derangement are usually ambulatory after a week or ten days, when they have regained normal voluntary control of the quadriceps motor mechanism (figs 3 and 4). For several days they walk with the aid of a chair, cane or crutch and after two or three weeks return to duty. I have been impressed with the unusually high percentage of normal knees following this system of treatment and the extremely small number of patients with recurrence of disability. This program of treatment diminishes the original period of disability, eliminates the use of all plaster splints and other forms of mechanical appliances, reduces recurrent disability and greatly reduces the necessity of surgical correction of knee joint disability as compared with other methods of treatment that I have used.

My associates and nurses and I are conscious of the Kenny syndrome. There may be a torn cartilage or a ruptured ligament in our patients as there may be an actual paralysis in some of Sister Kenny's patients, but they are made comfortable and their disability is relieved by a clear understanding of the Kenny syndrome and proper application of the Kenny system of treatment.

A chronic knee joint disability may or may not demand surgical treatment. Frequently the disability is relieved by the Kenny program, which corrects muscle spasm, contracture, mental alienation and incoordination. The same program not infrequently restores normal knee joint function in knees that have not been relieved of disability by surgical treatment.

Reginald Watson-Jones, the brilliant English surgeon, has made a plea to the medical profession to "re-develop the quadriceps."

Fig 4—The patient is now ready to become ambulatory. Muscle spasm pain flexion deformity and mental alienation of quadriceps muscle function have been relieved. Normal quadriceps function is demonstrated by complete extension of the knee against the resistance of gravity. Incoordination of muscle function is prevented with normal rhythmic action of both extensor and flexor muscle groups.

after knee joint injuries and restore the neuromuscular unit and prevent unnecessary disability. Sister Kenny has given to the medical profession a scientific explanation of quadriceps insufficiency and a system of treatment to correct or prevent it by relieving muscle spasm, alienation of muscle and incoordination of muscle function.

Station Hospital

INTESTINAL MOTILITY AND POSTOPERATIVE DISTENTION

EXPERIMENTAL AND CLINICAL STUDIES

CHARLES B. PUESTOW, M.D.

CHICAGO

Postoperative distention and gas pains frequently are dreaded more by patients advised to undergo surgical therapy than are the dangers of the operation itself. Many factors are known to contribute to these distressing complications. Intestinal obstruction may result from a variety of causes and produce pain and distention. Peritonitis with its associated inflammatory reaction of the intestine interferes with peristalsis, and distention follows. Surgical procedures on the bowel are followed by diminished motility of the operated segments often causing temporary partial obstruction. Rough handling of the bowel during an operation may produce the same results. However, in the majority of instances, distention and gas pains are not the result of a demonstrable organic complication but are thought to result from a "functional" disturbance of intestinal motility.

Experimental and clinical studies on the motor mechanism of the intestine have produced a great volume of scientific literature and many important observations. Much desired information, however, is still unknown. The normal habitat of the bowel within the peritoneal cavity and the disturbances in its physiology which result from exposing, transplanting or manipulating it to facilitate study make accurate observations difficult. Indirect methods of study often produce abnormal responses or may be difficult to interpret.

An ideal preparation for the study of intestinal motility would be one which would permit long and varied observations on the entire tract without altering the responses except as would normally occur under the varying physiologic and pharmacologic conditions of the experiment. It also should permit the satisfactory recording of these responses. The difficulty of securing such a preparation of organs which are situated normally within the body, and whose action is so easily altered by changes of habitat, psychic and nervous influences, anesthesia, operative trauma, alterations in circulation and various types of extraneous stimuli, is apparent.

Animal experimentation has yielded accurate information relative to bowel activities in various species. Many of these may be applied to man, others, because of differences in structure and function, may not. A review of studies which laid a groundwork for our present knowledge will not be attempted here. However, physicians owe much to the careful studies made on isolated strips of intestinal muscle, various isolated or transplanted segments of bowel, ingenious operations and mechanical devices to facilitate study and the utilization of the rare opportunities that sometimes afford unusual preparations for study. Many names are outstanding in this field of research, but to mention a few workers would be to neglect others who have contributed valuable information. We have conducted

many and varied experiments on the dog. Detailed discussion of them will not be included in this paper. A brief correlation of them with human studies will be made after the discussion of our clinical experiments.

Accurate observations on motility of the bowel in man have been more difficult to obtain than those in animals because less suitable preparations have been available for study. The open abdomen of surgical patients gives a clear view of the intestine, but the activity probably is altered by anesthesia, exposure to air, the influence of disease and the preoperative administration of drugs. A few investigations have been made by the introduction of balloons through the esophagus and anus and through fistulas in both the large and the small bowel. Hernial sacs containing bowel and thin abdominal scars have permitted direct observations of peristaltic activity, but the overlying skin or scar tissue usually does not allow a clear view of the underlying bowel or enable the observer to identify the portion of intestine being studied or orient it as to the direction of its activity or its relationship to associated segments. Many roentgen studies have been made by the use of opaque meals. In the colon such studies can give considerable information because the various portions of the large bowel can be identified easily and the slow nature of most muscular activity permits prolonged study. In the small bowel, however, orientation is much more difficult because of the length of the intestine, its multiple intermingled coils and the rapidity of its movements.

An unusual preparation permitting the study of intestinal motility in both the large and the small bowel of a patient was presented to me as the result of a number of surgical procedures and complications. The history of this patient is here given.

REPORT OF CASE

Miss L. B., aged 31, observed in 1928 a sudden severe hemorrhage from the urinary tract. She was hospitalized and under medical supervision improved rapidly and remained symptom free for more than three years. In 1931 she again experienced attacks of hematuria but with associated severe back pain at irregular intervals for about two years. A diagnosis of renal tuberculosis was made and nephrectomy on the right side was performed June 6, 1933 in another city. The diagnosis was not confirmed by microscopic studies of the kidney. After the operation pus and urine drained persistently from the incision. She was admitted to the Illinois Research and Educational Hospital Sept. 19, 1933 presenting a nephrectomy scar in the right lumbar region, unhealed in the anterior one third and discharging a brown purulent material. Although some urine drained through the fistula, she was voiding through the urethra. October 16 the fistulous tract was resected but complete healing failed to occur and a large amount of urine drained through the wound. This was urine secreted by the left kidney, which passed into the bladder and out through the patent right ureter. Jan. 29, 1934, a suprapubic cystostomy was performed. The right ureter was isolated and ligated at the bladder, and the vesical mucosa was oversewn after excision of the orifice of the fistula. Following this, urinary drainage through the sinus immediately ceased and the suprapubic wound healed. The patient was dismissed from the hospital on March 5 with the infected sinus healing and no leakage of urine.

May 26 she was readmitted to the hospital with a total fecal and urinary fistula at the site of the sinus in the anterior end of the original nephrectomy wound. The incision had been extended well around anteriorly and the fistula opened above and slightly anterior to the anterior superior spine of the ileum. My associates and I are of the opinion that perforation of the colon resulted from trauma induced by the patient and that the infection associated with the fecal fistula caused a reopening

of the bladder at the point at which the right ureter had formerly entered. Roentgen examination revealed that the fistula led into the midascending colon. The patient was then transferred to my service for closure of the fecal fistula.

Because of the large opening into the right colon, the extensive infection of the right flank and the possibility of a tuberculous infection existing (although this could never be demonstrated), it was decided to short circuit the fecal current from the right colon and later do a colectomy on the right side. June 21 a side to side anastomosis was made between the terminal ileum and the midtransverse colon. Two weeks later, evidently from self-induced trauma, the colon was separated from the abdominal wall at the site of the ascending colostomy, and several loops of small intestine eviscerated. These were replaced and the colostomy edge was sutured to the margin of the skin. Healing occurred without incident.

Some time later the abdomen was opened again through a right rectus incision for the purpose of removing the right colon. However, because of extensive infection and induration in the right side of the abdomen, it was decided only to isolate

As a result of the operations on this patient, her cecum and ascending colon were isolated from the remainder of the gastrointestinal tract, whose continuity had been reestablished by an anastomosis of the terminal ileum to the transverse colon (fig 1). A large defect existed in the right abdominal wall and connected directly with a large colostomy of the mid-ascending colon. A long right mesocolon permitted the entire cecum and most of the ascending colon to evaginate through the colostomy when the patient strained (figs 2, 3 and 4). Thus a large hernial sac was formed consisting of the right colon with its mucosa on the outside and the peritoneal covering or serosa of the colon forming the lining of the sac. Into this sac several loops of small intestine protruded. The large diameter of the colostomy which formed the neck of the hernial sac did not constrict the small intestine or interfere with its activity or blood supply. The single layer of colon wall that covered the small intestine was sufficiently thin to permit accurate observation of the motility and tonus of the underlying small bowel. Roentgen studies with barium by mouth and by enema revealed the location of the small intestine which entered the hernial sac to be the lower jejunum and upper ileum. Coincident with studies on the small bowel, motility of the right colon also could be observed. At the conclusion of an observation the hernia was reduced by having the patient turn on her left side, at which time the sac and its contents readily returned into the abdomen, where they could be maintained by a loose abdominal belt.

MOVEMENTS OF THE SMALL INTESTINE

The loops of small intestine observed in this patient, when checked by roentgen examination and subsequently at operation, appeared to be the lower part of the jejunum and the upper part of the ileum.

Several loops were visible in most studies. As much as 2 feet of bowel sometimes could be watched. The distal and proximal portions of each loop could be determined only by the direction of visible motion. Several types of activity were seen. Definite waves of rhythmic contraction coursing in one direction and occurring at the rate of eight to twelve a minute were commonly present. An area of dilatation usually was associated with one of constriction. However, sometimes the constriction seemed to precede the dilatation and at other times it appeared to follow it. The contraction sometimes would pass the length of the exposed segment but at other times would fade out after going a few centimeters. The rate was quite constant when the bowel was active, and an increase in motility was manifested chiefly by an increase in the regularity and strength of contractions rather than by an acceleration in rate. As motility increased the contractions appeared to be more progressive, giving the impression of a greater propulsive power. A second common type of motion usually associated with the rhythmic waves was a churning or to and fro activity.

Fig 1—A diagram of anatomic relationship when hernial sac protruded B position of right colon when replaced in abdominal cavity

completely the right colon from the remainder of the intestinal tract at this time. This was accomplished by dividing the ileum and transverse colon to the right of the previously made ileocolostomy and closing all four bowel ends. Recovery was satisfactory and in a few days all urinary drainage from the fistula ceased. The large opening into the ascending colon drained only a little mucus. The patient was dismissed and advised to return after several months for removal of the segment of right colon. On her return she presented such an interesting preparation for the study of intestinal motility that further surgery was delayed for more than two years to enable the accompanying observations to be made. During the greater part of this time the patient remained in the hospital and willingly cooperated. She was in good health throughout this period.

On Nov. 23, 1937 I removed the isolated right colon with comparative ease by reopening the anterior portion of the original nephrectomy wound, freeing the colostomy edge and then dividing the right mesocolon. No other pathologic condition was noted, and the wound was closed in layers. Recovery from this operation has been satisfactory. The specimen consisted of the appendix, cecum and entire ascending colon. The colostomy opening was 15 cm distal to the junction of the appendix and cecum.

of fairly short segments of bowel. Definite contraction rings did not appear in this motion, and frequently only a small portion of the circumference of the bowel seemed involved. Neither segmentation nor reverse peristalsis was observed. There appeared to exist a definite relationship between motility and tonus. When the bowel was inactive its tonus diminished, with a resulting enlargement in circumference. As motility increased the tonus became greater.

No relationship could be observed between feeding and motility of the small bowel. On some days the bowel seemed almost totally relaxed and inactive, on others it was vigorously active, although the time of day and meal relationship were the same. Feeding during an observation had no noticeable effect on activity.

MOVEMENTS OF THE COLON

Our observations on this patient were confined to the cecum and proximal half of the ascending colon. The colostomy opening, which was 15 cm from the base of the appendix, permitted the complete eversion of colon proximal to it and from 10 to 15 cm of colon

Fig 2—Colostomy opening with right colon in abdominal cavity

distal to it. The entire segment was turned inside out, with the mucosa forming the outer layer. This position, of course, was abnormal but did not appear to alter the muscular activity. Although intestinal contents did not enter the right colon, the exposed segment could be filled with loops of small bowel and distended to any desired degree by increasing intra-abdominal tension. In this manner the mechanical factor of distention could be simulated. The bowel remained a healthy color, continued to secrete mucus and responded similarly in frequent studies throughout two years of observation.

Inactivity was the most characteristic feature of this segment of proximal colon. For hours at a time no appreciable amount of motility was seen. Small superficial areas of contraction were more or less constant. These could conceivably have a churning action but could not cause progress of bowel contents. At times the segment hung limp with almost a complete loss of tone. During these periods the small churning movements were weak or absent. At other times the tonus was improved and the ripple-like contractions were stronger and more frequent. With a still greater increase in tone the contractions became more diffuse and simulated to some degree pendulum movements. However, definite contraction rings did not form.

Occasionally, during hours of observation, one or more strong generalized contractions were seen. These were very slow but powerful contractions. In most instances they began in the cecum, which contracted as a unit.

Fig 3—Hernial sac protruding showing loops of small intestine covered by right colon

The wave of contraction then would travel very slowly up the ascending colon, the cecum usually remaining firmly contracted. The strength of contractions was sufficiently great to replace completely into the abdomen the contained loops of small intestine. The time required from the onset of the wave in the cecum until the entire exposed segment was firmly contracted was usually one to three minutes. The bowel often remained in a tonic state of contraction for periods of time up to several minutes thereafter. Relaxation sometimes occurred gradually and at other times suddenly, with the bowel becoming very atonic. Occasionally two or three similar contractions would succeed one another in a brief lapse of time. It was rare to see a single contraction or a series of contractions of this nature more than once during any one observation period.

Fig 4—Appearance of patient with bowel exposed

Occasionally a contraction of the colon would begin as a constricting ring at the junction of the cecum and ascending colon. When this occurred, the cecum sometimes contracted as a unit shortly thereafter, but at other times it would remain distended, the contraction ring preventing it from emptying itself of its contents. The wave would progress up the ascending colon in a manner similar to that seen when contractions originated in the cecum. No other form of peristalsis and no reverse peristalsis were seen in the right colon.

The patient was observed after fasts of varying duration and was fed during observations to note the influence of feeding on the activity of the proximal colon. Occasionally soon after eating a slow progressive mass contraction would occur, but this was so infrequent as to lead us to conclude that a gastrocolic reflex was uncommon in this patient. There did not appear to be a definite relationship of contractions of the colon to fasting, feeding or time of day. Pinching the mucosa frequently would elicit strong contractions, but distention of the segment by forcing more small intestine into the colon did not initiate this response.

RELATIONSHIP OF SMALL AND LARGE BOWEL MOTILITY

A very definite relationship was noted between the motility of the small intestine and that of the right colon. When the small bowel was contracting vigorously the colon showed little or no activity and appeared atonic. When the colon became active the visible small intestine showed a definite diminution in tone and became larger in diameter, and its muscular activity became definitely diminished and at times almost ceased. It was not uncommon for both the small intestine and the right colon simultaneously to show little or no motility, but it was extremely rare for the two to be vigorously active at the same time. Since the duodenum, upper part of the jejunum and terminal portion of the ileum were not visible, their activity was not ascertained, but it was very obvious that there was an antagonistic activity between the midportion of the small intestine and the right colon. When the former was active the latter was definitely quiet and, conversely, when the right colon was contracting there was an inhibition of both motility and tonus of the small bowel.

ACTION OF DRUGS ON INTESTINAL MOTILITY

Since the small and large intestine could be observed simultaneously in this patient, she provided an excellent opportunity for the study of the influence of various drugs on the motor activity of the bowel. A number of drugs commonly used on surgical patients were employed.

Morphine sulfate was administered hypodermically in doses of $\frac{1}{2}$ grain (0.01 Gm.). Muscular changes in the bowel became evident in from five to fifteen minutes. The small intestine showed a gradual increase in tonus and in motility. This increase was progressive and reached a maximum in fifteen to thirty minutes after the drug was injected. Both the churning motion and the progressive rhythmic waves increased in strength and regularity. Although the rhythmic peristaltic waves showed little change in rate, they occurred regularly with few, if any, rest periods. The small bowel appeared to have a decided increase in propulsive power as well as in mixing activity. This increase in activity continued for one or two hours or longer and gradually subsided to normal. A secondary depression in motility was not noted although observations were continued for several hours. In a number of experiments a second administration of morphine was given two hours after the first. Occasionally a further increase in motility was noted if maximum contractions did not follow the first injection. The duration of stimulation was prolonged in most instances. Again secondary depression was not noted. Of all the drugs employed, morphine had the most constant and greatest stimulating influence on the small bowel. Injections of morphine were always followed by a relaxation and

a decided diminution or complete cessation of motility of the right colon. Mass contractions were not seen. What activity occurred was of the small churning type of local waves, weak and nonpropulsive. The degree of tonus and motility of the right colon was inversely proportional to that seen in the small intestine.

Physostigmine salicylate was administered in doses of $\frac{1}{10}$ grain (13 mg.) both subcutaneously and intramuscularly. An increase in tonus and motility of the small intestine was noted, but this response was mild and inconstant. The right colon was not greatly altered but contractions were not seen following the use of this drug and relaxation was frequently observed. Almost invariably nausea and vomiting were induced, and circulatory disturbances were manifested.

Prostigmine methylsulfate in doses of 1 cc. of 1:2,000 and of 1:4,000 solution was used on many occasions. The results were uniform and constant. In from five to twenty minutes a definite increase in tonus and motility of the small intestine was noted. Contractions were both of the local churning and of the progressive peristaltic type. The latter were regular in rhythm and of maximum rate. Local spasms were not seen, and peristalsis always appeared to be of a progressive propulsive character. The patient was not conscious of any discomfort, cramping or intestinal activity. The stimulation of motility was nearly as great as that following the use of morphine and was greater than that produced by any other drug employed. It continued for one-half hour to several hours and gradually returned to normal. Secondary depression was not noted.

In contrast to its stimulating effect on the small intestine, prostigmine methylsulfate definitely inhibited the cecum and ascending colon. Contractions of this portion of the bowel did not occur for many hours after the injection of the drug. The tonus of the right colon greatly diminished and remained so throughout the period of time that the small intestine was active. This inhibitory effect on the right colon corresponded to that produced by all drugs which stimulated the small bowel.

Both acetylcholine and mecholyl chloride were given to our patient subcutaneously. Occasionally a slight stimulation of the motility and an increased tonus of the small intestine were noted. Frequently no effect was seen. The colon was never stimulated by these drugs.

Solution of posterior pituitary in doses of 1 and 2 cc. and pitressin in doses of 10 and 20 pressor units were administered subcutaneously. The character of the response to the two drugs was similar, varying only in degree and duration. The time interval between the injection and the onset of visible effects was from three to thirty minutes, most frequently in ten to twenty minutes. The maximum effects were noted ten to twenty minutes later. Results were so constant and uniform as to leave no doubt in the minds of the observers as to the influence of these drugs. When the small intestine was quiet no change occurred in its motility following the administration of solution of posterior pituitary. Under these circumstances occasional diminution in tonus was the only noticeable effect. When the small bowel showed visible churning and peristaltic activity, the administration of solution of posterior pituitary or pitressin was followed by an inhibition or cessation of motility and a diminution in tonus, with a resultant dilatation of the bowel. These results occurred with the smaller dose of the drugs as well as with the larger. Pitressin produced a greater

degree of inhibition than did solution of posterior pituitary. This inhibitory influence usually persisted for one or two hours, after which the small bowel would return to its former state of activity. There was no definite secondary stimulation noted.

The reactions of the cecum and ascending colon were very different from those of the small bowel. In five to twenty-five minutes after the injection of solution of posterior pituitary or pitressin, strong contractions of the colon almost invariably set in. During most observations these began by a gradual contraction of the entire cecum as a unit. There appeared to be a definite functional line of demarcation between the cecum and the ascending colon located at about the level of the ileocecal junction. Following the contraction of the cecum a slow, strong, progressive contraction spread up the ascending colon, often requiring several minutes to involve all of the exposed bowel. Sometimes the cecum would begin to relax before the most distal portion of the ascending colon was completely contracted. At other times the entire segment remained in a state of tonic contraction for several minutes and then suddenly and completely relaxed as a unit. On rare occasions the contraction began at the ileocecal junction, forming a definite constricting band. Sometimes when this occurred contraction of the cecum followed, at other times, although the cecum appeared to be trying to contract, the constricting band prevented it from emptying itself of its contents. When the constricting band at the ileocecal junction occurred, the contraction slowly progressed up the ascending colon. Sometimes, following a strong progressive contraction, the bowel remained totally relaxed for a few minutes, after which a second similar contraction would occur. At other times there was a persistent increase in tonus and an increase in the churning type of muscular activity. When this occurred peristaltic contractions often began, sometimes strongly and at other times weakly, sometimes going on to a complete contraction and at other times subsiding after only partially contracting the bowel. The duration of this increased activity was from a few minutes to an hour or longer. Usually only a few of the powerful and complete contractions occurred. The reaction of the right colon to pitressin was far more constant and pronounced than to surgical solution of posterior pituitary. Ten pressor units of pitressin produced stronger contractions than did 2 cc of solution of posterior pituitary. The opposite effect of these drugs on the large and small bowel was very apparent.

Atropine sulfate was administered to this patient subcutaneously in doses of $\frac{1}{150}$ gram (0.4 mg). Within a few to twenty minutes there was a definite decrease in tonus of the small bowel and some inhibition of motility. Both the peristaltic type of contractions and the local churning movements continued but were less frequent and forceful. The inhibiting effect on the small bowel was not as pronounced as was that seen following the use of solution of posterior pituitary or pitressin. The effect of atropine on the right colon was less noticeable. Frequently there seemed to be a definite diminution of tonus, at other times there was little apparent change. The small churning contractions were not entirely abolished. Occasionally a strong peristaltic contraction of the cecum and ascending colon was seen. Although atropine appeared to have a slightly inhibitory influence on the musculature of the right colon, it was not constant and was less pronounced than was that noted in the small bowel.

When atropine was combined with morphine there was little change in the tonus or motility of the intestine. To correspond with the doses frequently used on surgical patients, morphine sulfate $\frac{1}{6}$ grain (0.01 Gm) and atropine sulfate $\frac{1}{150}$ grain (0.4 mg) were given subcutaneously. Occasionally a slight stimulation of the small intestine with a corresponding inhibition of the right colon was noted. This was never as severe as when morphine alone was used. At other times no stimulation was noted. Definite inhibition of the small bowel was not noted following this combination of drugs.

In summary, morphine sulfate, prostigmine methylsulfate and, to a lesser degree, physostigmine and the choline derivatives produced a definite increase in tonus and motility of the small intestine and had an inhibiting influence on the motility of the right colon. Acting in a totally contrary manner, solution of posterior pituitary and pitressin inhibited the muscular action of the small bowel but produced powerful contractions of the right colon.

STUDIES ON OTHER HUMAN SUBJECTS

In an effort to determine whether the reactions recorded were peculiar to this patient or are normal human responses, in an attempt to locate the area of bowel in which reactions change from stimulation to inhibition and the reverse and with the purpose of observing whether the remainder of the colon reacts as does the right colon, studies were conducted on 13 other patients. Three of these had portions of ileum exposed to direct vision, 2 having segments of terminal ileum exteriorized at the time of resection of the right colon for carcinoma and the third having a segment several feet proximal to the ileocecal valve exteriorized during an operation for intestinal obstruction. The other 10 patients all had had resections of the colon for carcinoma. At operation an effort was made to exteriorize long segments of adjacent colon to permit direct observations. Four segments of transverse colon and six segments of the sigmoid were exteriorized in this manner. After the patients had recovered from the effects of operative trauma and all inflammatory reaction had subsided, repeated observations of the motility of the exposed segments and the influence of drugs on them were made by Mr. James V. Cairns.

TERMINAL ILEUM

In all experiments the subcutaneous administration of morphine sulfate in doses of $\frac{1}{6}$ or $\frac{1}{4}$ grain (0.01 or 0.016 Gm) was followed by pronounced increase in tonus and motility of the exposed ileum lasting two or more hours. An increase in the passage of flatus and feces indicated that the small bowel proximal to the exposed segment also was stimulated. Prostigmine methylsulfate likewise produced a decided increase in the motility and tonus of the terminal ileum in all observations. The effects of pitressin on the terminal ileum were not constant. In most observations depression of both tonus and motility followed its use, but in a few instances increased activity was noted. However, all patients reported fewer evacuations from the ileostomies following the administration of pitressin, suggesting a depression of the small bowel proximal to the opening.

COLON

The exposed segments of transverse and sigmoid colon responded in an identical manner to the drugs employed. When the colon was visibly active and contracted, morphine caused a depression of both motility and tonus. Strong contractions never were seen after

The patient was observed after fasts of varying duration and was fed during observations to note the influence of feeding on the activity of the proximal colon. Occasionally soon after eating a slow progressive mass contraction would occur, but this was so infrequent as to lead us to conclude that a gastrocolic reflex was uncommon in this patient. There did not appear to be a definite relationship of contractions of the colon to fasting, feeding or time of day. Pinching the mucosa frequently would elicit strong contractions, but distention of the segment by forcing more small intestine into the colon did not initiate this response.

RELATIONSHIP OF SMALL AND LARGE BOWEL MOTILITY

A very definite relationship was noted between the motility of the small intestine and that of the right colon. When the small bowel was contracting vigorously the colon showed little or no activity and appeared atonic. When the colon became active the visible small intestine showed a definite diminution in tone and became larger in diameter, and its muscular activity became definitely diminished and at times almost ceased. It was not uncommon for both the small intestine and the right colon simultaneously to show little or no motility, but it was extremely rare for the two to be vigorously active at the same time. Since the duodenum, upper part of the jejunum and terminal portion of the ileum were not visible, their activity was not ascertained, but it was very obvious that there was an antagonistic activity between the midportion of the small intestine and the right colon. When the former was active the latter was definitely quiet and, conversely, when the right colon was contracting there was an inhibition of both motility and tonus of the small bowel.

ACTION OF DRUGS ON INTESTINAL MOTILITY

Since the small and large intestine could be observed simultaneously in this patient, she provided an excellent opportunity for the study of the influence of various drugs on the motor activity of the bowel. A number of drugs commonly used on surgical patients were employed.

Morphine sulfate was administered hypodermically in doses of $\frac{1}{8}$ grain (0.01 Gm.) Muscular changes in the bowel became evident in from five to fifteen minutes. The small intestine showed a gradual increase in tonus and in motility. This increase was progressive and reached a maximum in fifteen to thirty minutes after the drug was injected. Both the churning motion and the progressive rhythmic waves increased in strength and regularity. Although the rhythmic peristaltic waves showed little change in rate, they occurred regularly with few, if any, rest periods. The small bowel appeared to have a decided increase in propulsive power as well as in mixing activity. This increase in activity continued for one or two hours or longer and gradually subsided to normal. A secondary depression in motility was not noted although observations were continued for several hours. In a number of experiments a second administration of morphine was given two hours after the first. Occasionally a further increase in motility was noted if maximum contractions did not follow the first injection. The duration of stimulation was prolonged in most instances. Again secondary depression was not noted. Of all the drugs employed, morphine had the most constant and greatest stimulating influence on the small bowel. Injections of morphine were always followed by a relaxation and

a decided diminution or complete cessation of motility of the right colon. Mass contractions were not seen. What activity occurred was of the small churning type of local waves, weak and nonpropulsive. The degree of tonus and motility of the right colon was inversely proportional to that seen in the small intestine.

Physostigmine salicylate was administered in doses of $\frac{1}{50}$ grain (1.3 mg.) both subcutaneously and intramuscularly. An increase in tonus and motility of the small intestine was noted, but this response was mild and inconstant. The right colon was not greatly altered but contractions were not seen following the use of this drug and relaxation was frequently observed. Almost invariably nausea and vomiting were induced, and circulatory disturbances were manifested.

Prostigmine methylsulfate in doses of 1 cc. of 1:2,000 and of 1:4,000 solution was used on many occasions. The results were uniform and constant. In from five to twenty minutes a definite increase in tonus and motility of the small intestine was noted. Contractions were both of the local churning and of the progressive peristaltic type. The latter were regular in rhythm and of maximum rate. Local spasms were not seen, and peristalsis always appeared to be of a progressive propulsive character. The patient was not conscious of any discomfort, cramping or intestinal activity. The stimulation of motility was nearly as great as that following the use of morphine and was greater than that produced by any other drug employed. It continued for one-half hour to several hours and gradually returned to normal. Secondary depression was not noted.

In contrast to its stimulating effect on the small intestine, prostigmine methylsulfate definitely inhibited the cecum and ascending colon. Contractions of this portion of the bowel did not occur for many hours after the injection of the drug. The tonus of the right colon greatly diminished and remained so throughout the period of time that the small intestine was active. This inhibitory effect on the right colon corresponded to that produced by all drugs which stimulated the small bowel.

Both acetylcholine and meclochol chloride were given to our patient subcutaneously. Occasionally a slight stimulation of the motility and an increased tonus of the small intestine were noted. Frequently no effect was seen. The colon was never stimulated by these drugs.

Solution of posterior pituitary in doses of 1 and 2 cc. and pitressin in doses of 10 and 20 pressor units were administered subcutaneously. The character of the response to the two drugs was similar, varying only in degree and duration. The time interval between the injection and the onset of visible effects was from three to thirty minutes, most frequently in ten to twenty minutes. The maximum effects were noted ten to twenty minutes later. Results were so constant and uniform as to leave no doubt in the minds of the observers as to the influence of these drugs. When the small intestine was quiet no change occurred in its motility following the administration of solution of posterior pituitary. Under these circumstances occasional diminution in tonus was the only noticeable effect. When the small bowel showed visible churning and peristaltic activity, the administration of solution of posterior pituitary or pitressin was followed by an inhibition or cessation of motility and a diminution in tonus, with a resultant dilatation of the bowel. These results occurred with the smaller dose of the drugs as well as with the larger. Pitressin produced a greater

degree of inhibition than did solution of posterior pituitary. This inhibitory influence usually persisted for one or two hours, after which the small bowel would return to its former state of activity. There was no definite secondary stimulation noted.

The reactions of the cecum and ascending colon were very different from those of the small bowel. In five to twenty-five minutes after the injection of solution of posterior pituitary or pitressin, strong contractions of the colon almost invariably set in. During most observations these began by a gradual contraction of the entire cecum as a unit. There appeared to be a definite functional line of demarcation between the cecum and the ascending colon located at about the level of the ileocecal junction. Following the contraction of the cecum a slow, strong, progressive contraction spread up the ascending colon, often requiring several minutes to involve all of the exposed bowel. Sometimes the cecum would begin to relax before the most distal portion of the ascending colon was completely contracted. At other times the entire segment remained in a state of tonic contraction for several minutes and then suddenly and completely relaxed as a unit. On rare occasions the contraction began at the ileocecal junction, forming a definite constricting band. Sometimes when this occurred contraction of the cecum followed, at other times, although the cecum appeared to be trying to contract, the constricting band prevented it from emptying itself of its contents. When the constricting band at the ileocecal junction occurred, the contraction slowly progressed up the ascending colon. Sometimes, following a strong progressive contraction, the bowel remained totally relaxed for a few minutes, after which a second similar contraction would occur. At other times there was a persistent increase in tonus and an increase in the churning type of muscular activity. When this occurred peristaltic contractions often began, sometimes strongly and at other times weakly, sometimes going on to a complete contraction and at other times subsiding after only partially contracting the bowel. The duration of this increased activity was from a few minutes to an hour or longer. Usually only a few of the powerful and complete contractions occurred. The reaction of the right colon to pitressin was far more constant and pronounced than to surgical solution of posterior pituitary. Ten pressor units of pitressin produced stronger contractions than did 2 cc of solution of posterior pituitary. The opposite effect of these drugs on the large and small bowel was very apparent.

Atropine sulfate was administered to this patient subcutaneously in doses of $\frac{1}{150}$ grain (0.4 mg). Within a few to twenty minutes there was a definite decrease in tonus of the small bowel and some inhibition of motility. Both the peristaltic type of contractions and the local churning movements continued but were less frequent and forceful. The inhibiting effect on the small bowel was not as pronounced as was that seen following the use of solution of posterior pituitary or pitressin. The effect of atropine on the right colon was less noticeable. Frequently there seemed to be a definite diminution of tonus, at other times there was little apparent change. The small churning contractions were not entirely abolished. Occasionally a strong peristaltic contraction of the cecum and ascending colon was seen. Although atropine appeared to have a slightly inhibitory influence on the musculature of the right colon, it was not constant and was less pronounced than was that noted in the small bowel.

When atropine was combined with morphine there was little change in the tonus or motility of the intestine. To correspond with the doses frequently used on surgical patients, morphine sulfate $\frac{1}{6}$ grain (0.01 Gm) and atropine sulfate $\frac{1}{150}$ grain (0.4 mg) were given subcutaneously. Occasionally a slight stimulation of the small intestine with a corresponding inhibition of the right colon was noted. This was never as severe as when morphine alone was used. At other times no stimulation was noted. Definite inhibition of the small bowel was not noted following this combination of drugs.

In summary, morphine sulfate, prostigmine methylsulfate and, to a lesser degree, physostigmine and the choline derivatives produced a definite increase in tonus and motility of the small intestine and had an inhibiting influence on the motility of the right colon. Acting in a totally contrary manner, solution of posterior pituitary and pitressin inhibited the muscular action of the small bowel but produced powerful contractions of the right colon.

STUDIES ON OTHER HUMAN SUBJECTS

In an effort to determine whether the reactions recorded were peculiar to this patient or are normal human responses, in an attempt to locate the area of bowel in which reactions change from stimulation to inhibition and the reverse and with the purpose of observing whether the remainder of the colon reacts as does the right colon, studies were conducted on 13 other patients. Three of these had portions of ileum exposed to direct vision, 2 having segments of terminal ileum exteriorized at the time of resection of the right colon for carcinoma and the third having a segment several feet proximal to the ileocecal valve exteriorized during an operation for intestinal obstruction. The other 10 patients all had had resections of the colon for carcinoma. At operation an effort was made to exteriorize long segments of adjacent colon to permit direct observations. Four segments of transverse colon and six segments of the sigmoid were exteriorized in this manner. After the patients had recovered from the effects of operative trauma and all inflammatory reaction had subsided, repeated observations of the motility of the exposed segments and the influence of drugs on them were made by Mr. James V. Carris.

TERMINAL ILEUM

In all experiments the subcutaneous administration of morphine sulfate in doses of $\frac{1}{6}$ or $\frac{1}{4}$ grain (0.01 or 0.016 Gm) was followed by pronounced increase in tonus and motility of the exposed ileum lasting two or more hours. An increase in the passage of flatus and feces indicated that the small bowel proximal to the exposed segment also was stimulated. Prostigmine methylsulfate likewise produced a decided increase in the motility and tonus of the terminal ileum in all observations. The effects of pitressin on the terminal ileum were not constant. In most observations depression of both tonus and motility followed its use, but in a few instances increased activity was noted. However, all patients reported fewer evacuations from the ileostomes following the administration of pitressin, suggesting a depression of the small bowel proximal to the opening.

COLON

The exposed segments of transverse and sigmoid colon responded in an identical manner to the drugs employed. When the colon was visibly active and contracted, morphine caused a depression of both motility and tonus. Strong contractions never were seen after

the use of this drug. When the colon was relaxed and inactive no change was noted after the injection of morphine. Prostigmine methylsulfate likewise was found to produce a definite diminution of both motility and tonus of the colon. Atropine also diminished colon contractions and tonus. Contrarily, pitressin produced a decided increase in the tonus and motility of all exposed segments of the colon. Pitressin in oil produced a similar effect on the colon. The onset of stimulation was delayed longer, but its duration was considerably increased. Repeated daily injections of this drug had a definite cumulative effect on motility of the colon.

The observations on these additional patients substantiate to a great degree the conclusions reached in our studies on the patient mentioned earlier. Those drugs, especially morphine and prostigmine methylsulfate which stimulate motility of the small bowel, have an inhibiting effect on the colon. Pitressin is a powerful stimulant to the entire colon from the cecum to the sigmoid but diminishes motor activity of the small bowel. The transverse and sigmoid colon responds to all stimuli in a manner similar to the cecum and ascending colon.

It is difficult to determine at what level of the bowel a drug produces stimulation proximally and inhibition distally, or the contrary. It evidently is not at the ileocecal junction. We believe that this change is a gradual transition occurring in the lower foot or two of ileum.

COMPARISON OF INTESTINAL MOTILITY IN MAN AND DOG

Results of studies by other observers and of our own observations reveal several similarities and differences in the motility of the bowel of man and dog. The small intestine of these species has a comparatively similar structure and function. That of the dog is shorter and accomplishes the function of digestion and assimilation more completely for equal lengths of gut, but this would be expected because of the more concentrated nature of its food. The character of movements is quite similar. An increased motility following feeding is more apparent in the dog than in man. The action of various drugs employed under these conditions of experimentation were identical.

The motility of the colon of man and dog, however, varies greatly. This would be expected because of the differences in function and in anatomic structure. Man has a well developed proximal colon while the dog has a short colon which functionally is chiefly distal colon. Greater absorption of water takes place in the small intestine of the dog, and there is less need for prolonged retention in the proximal colon.

Those drugs which stimulated motility in the small bowel of man, namely morphine, prostigmine methylsulfate, physostigmine and mechoyl, had a definite and constant inhibiting influence on the tonus and motility of the colon. In the dog the same inhibition of the colon was not noted. Morphine increased both the tonus and the peristalsis. This can explain the frequent bowel evacuation following the administration of morphine to dogs. Prostigmine methylsulfate strongly contracted the dog's entire colon, sometimes producing spasms. This was never seen in our patients. Those drugs which caused strong and repeated contractions of the human colon, namely solution of posterior pituitary and pitressin, did not produce the same response in the colon of the dog. Although at times there was a slight suggestion of increased activity, in most studies stimulation could not be detected.

FACTORS PRODUCING POSTOPERATIVE DISTENTION

The information learned from these observations suggests a number of factors which may be responsible for the development of postoperative distention and gas pains. It is routine practice to administer morphine to patients before and for one or two days after operation. This maintains a constant stimulation to motility of the small bowel but inhibits colon contractions. Except when intestinal obstruction, peritonitis or paralytic ileus exists, postoperative distention is due to gas in the colon. This fact is substantiated by roentgenograms. It is likely that the paralyzing effect of morphine on the colon prevents this organ from contracting and permits it to become overdistended with gas.

The prevention and relief of pain are essential to surgical patients, and the opiates are most satisfactory to accomplish this. However, it usually is unnecessary to continue their administration for more than a few hours after operation. By discontinuing their use as early as possible, the colon usually will recover its tonus and motility before distention occurs. If the prolonged use of morphine is indicated, its pharmacologic action on the bowel may be counteracted by the use of small doses of solution of posterior pituitary. This drug is of value also in treating distention which is confined to the colon.

Fortunately paralytic ileus is a less frequent complication of surgery. When it is due to a diffuse peritonitis it is doubtful whether the intestine will respond to any type of stimulation in the early stages. Distention then is best combated by keeping the gastrointestinal tract as empty as possible by the use of constant suction in the duodenum or farther down the small bowel. The colon should also be kept empty by means of enemas or suction applied to colon tubes. When recovery from peritonitis begins, motility of the small bowel often can be encouraged by the use of drugs which have a stimulating action on it. Prostigmine methylsulfate is of value here unless there is some indication for the use of morphine. These drugs in combination with suction are of value also in treating paralytic ileus not due to peritonitis.

By an understanding of the normal physiology of intestinal motility, the causes of its disturbances and the action of various drugs on it, one can avoid much postoperative discomfort and can institute rational treatment of postoperative distention.

SUMMARY

Human intestinal motility has been studied on a number of patients who, as the result of surgical procedures, have had various portions of the small and large intestine exposed, permitting direct visual observation.

A contrary motility between small and large bowel has been noted. When the small bowel is vigorously contracting, the colon is inactive. When the colon contracts, the small intestine appears to be inhibited.

Those drugs, including the opiates, physostigmine, prostigmine methylsulfate and the choline derivatives, which stimulate motility of the small bowel inhibit the colon.

Solution of posterior pituitary and pitressin produce powerful contractions of the colon but diminish motility of the small bowel.

Postoperative distention may be due to the paralyzing action of morphine on the colon.

25 East Washington Street

FIVE YEAR CONTROL OF BLADDER
CANCERS BY RADON IMPLANTS

BENJAMIN S. BARRINGER, MD

NEW YORK

There is no body cancer which is as well adapted for attack by radon implants as bladder carcinomas. Notwithstanding that these tumors are radiosensitive, their accessibility to cystoscopic view and suprapubic exposure, their long confinement to the bladder, the flexibility of radon seed implantation and the possibility of early diagnosis all contribute to place bladder cancers in a unique class for control by radon implants.

Cystoscopy in a fourth of all cases offers a means of both seeing and imprinting the entire tumor. Because of size, position or bleeding, three fourths of all bladder cancers have to be subjected to suprapubic cystotomy, both to view completely and implant accurately the tumor with radon seeds. Such an operation has a relatively low mortality, 5 per cent as top, 3 per cent as low, if cases are carefully worked up.

Papillary cancers of the bladder are confined to the bladder for a long period and are generally slow to metastasize. Because of this there ought to be a high percentage of five year cures. The fact that most of them are situated in the base of the bladder contiguous to ureters and urethra has made surgical removal difficult, hazardous and in many cases impossible. This accounts for the growing popularity among urologists of the operation of total cystectomy. What has been a hindrance to surgery has been a help to radon implantation. The base of the bladder is practically immobile as contrasted with the constantly mobile upper bladder. In the male underneath the bladder base is the prostate and the tissues beneath the trigone. This gives a substantial depth of tissue to back up the radon seed implants. In the female there is less depth of tissue, and radon implants have of necessity to be more superficial.

Infiltrating cancers are quite different. Often they do not show the early hematuria of papillary cancers, they readily grow through the bladder wall and metastasize early. Because they do metastasize early I cannot see that total cystectomy can offer any more than radon implants. Both are at a disadvantage. If the infiltrating tumor has grown through the bladder wall, radon implantation has, I believe, an equal chance with total cystectomy of cure. There is the much higher mortality of the latter to be considered.

Of 257 personal cases of bladder cancers seen up to and including the year 1937, 112 were papillary cancers and 145 infiltrating cancers. Of the 112 papillary tumors 3 were operated on palliatively, and of the 145 infiltrating tumors 12 were either not operated on at all or operated on for palliation. These 15 cases are excluded from the statistics because some of them had metastasis, in some the bladder was merely felt through the suprapubic opening and in some radon was implanted because of hematuria.

This leaves us with 109 papillary tumors and 133 infiltrating tumors. Of the 109 patients with papillary tumors the bladder tumors of 20 were proved cured, but they died of some intercurrent disease or were lost track of before the five year period.

The same was true of 12 of the 133 infiltrating tumors. This leaves us with the following percentage of five year cures:

Of 89 patients with papillary cancer there were 50, or 56.1 per cent, who were well for five years.

Of 121 patients with infiltrating cancer there were 35, or 28.9 per cent, who were well for five years.

Of 210 patients with combined papillary and infiltrating cancer, 85, or 40.4 per cent, were well for five years.

PATHOLOGY

The pathologic diagnosis in all these cases has been made by examining pieces of the tumor obtained either cystoscopically or at the suprapubic exposure. It is never possible to obtain the entire tumor with its base for examination. Because of this the diagnosis has been modified by the clinical observations. If a tumor is reported as papillary cancer and if at operation the base of the tumor is found to be indurated, that tumor is classed as infiltrating rather than papillary cancer. Such induration is gaged both by the actual feel and by the sense of resistance felt by the needle bearing radon seeds. These two methods are extremely accurate in determining induration and therefore classifying the tumor as infiltrating.

In 17 cases there was no pathologic diagnosis or a diagnosis of papilloma. But 3 of these 17 are reported as five year cures. Thirteen patients died of cancer and 1 was lost track of. This indicates that the clinical diagnosis in these 17 cases was accurate.

In our series "papillomas with atypical cells" were classed as papillary carcinoma. The malignancy in this class of cases has been doubted by some pathologists and urologists. There is no question that a small percentage of these tumors have been easily cured by various methods, such as fulguration, excision and roentgen rays, and do not act like malignant tumors. By far the larger percentage, however, have all the attributes of real malignancy. They react badly or not at all to fulguration and they tend stubbornly to recur. There is no pathologic or clinical means whereby one may distinguish between these two groups, and until there is it is only fair and safe to group them under one class, papillary cancer.

THE SUPRAPUBIC OPERATION

There have been some slight modifications of the suprapubic operation for the implantation of radon seeds as described some years ago. Perhaps the most important is the use of sulfathiazole crystals following the implantation, both in the bladder and in the suprapubic wound. Many of these tumors are badly infected. If the infection can be limited by the use of sulfathiazole, much has been gained. Second, the radon seeds are not as strong (between 1 and 1.5 millicuries) and are not planted as near together as formerly: one seed to 1 square centimeter. Also if the tumor base is badly indurated the seeds are not planted as deeply as formerly, not more than 1 cm in depth.

If the tumor is directly over one ureter orifice and there is both hydronephrosis and hydronephrosis, then an attempt is made to place a large ureteral catheter (8 F) in the ureter at the time of the cystotomy operation. This is left in place several days. By this means it has been possible to save some kidneys and prevent an infection of a hydronephrotic kidney.

A case in point is as follows:

J. J., a man admitted to the Memorial Hospital on Oct. 17, 1939, was shown by cystoscopy to have an extensive bladder

carcinoma centering over the left ureteral orifice. The orifice could not be identified. Pathologic examination revealed "epidermoid carcinoma grade 3." The intravenous pyelogram showed a left hydroureter and left hydronephrosis. A suprapubic cystotomy was done and a papillary tumor 4 by 3 cm in diameter was seen and implanted with radon gold seeds totaling 32.97 millicuries (4395 millicurie hours). An 8 F catheter was inserted into the left ureter, the end being brought out of the suprapubic wound, and left in place for three days. The highest postoperative temperature was 102 F. This gradually dropped and became normal eight days after operation. On April 3, 1940 an intravenous pyelogram showed no hydronephrosis and but a moderate dilatation of the left ureter for a short distance above the bladder. A 6 F catheter was passed with some difficulty up the left ureter. He had no tumor. In January 1942 his condition was excellent.

All in all we are cutting down infectious slough of the tumor base and bladder, infection of the suprapubic wound and infection of the kidneys.

DETAILS OF 257 CANCERS OF BLADDER

Size of Base—In 235 of the 257 cancers there are definite records of the size of the tumor base. But 5 were less than 2 sq. cm., 92 were from 2 to 10 sq. cm. and 138 (58 per cent) were more than 10 sq. cm. This indicates the large size most bladder tumors reach by the time they are seen at the hospital.

Situation—The site of the tumor was stated in 243 cases. Of these 195 (80 per cent) were on the bladder base involving or near the internal urethra or one or both ureters.

Patients Well Over Ten Years—Twenty-one patients are well after the lapse of ten years or more. The oldest patient was well for some twenty-two years, when she died at the age of 92.

Kind of Treatment—Suprapubic implantation was done 183 times and cystoscopic implantation 89 times in the 257 cases. These figures indicate that in 85 cases a combination of suprapubic and cystoscopic implantation was done to control the tumor. An attempt to cure bladder tumors by means of cystoscopic implantation of radon seeds should be made in all cases in which the tumor is in a position to be readily seen in its entire extent and when the tumor is not too large. This applies to both papillary and infiltrating growths.

Complications of Radon Seed Implantation—Stone formation on the dead tumor base is probably the most important complication. This means careful and repeated cystoscopy and removal of any calcareous deposits by the cystoscopic forceps. Occasionally the stone has to be crushed and washed out with a stone evacuator. And in a very few I have had to remove a stone by suprapubic cystotomy.

I have had 2 cases in which vesicovaginal fistula followed the radon seed implantation. One of these patients died at the end of five years of cancer and 1 was cancer free when she died at the end of five years of a kidney complication.

Surgery of Bladder Tumors—There is no doubt in the mind of any urologist that the surgical removal of many bladder cancers is entirely possible. As far as my point of view goes the tumors of the bladder vault do best following surgical excision. These are apt to be highly malignant and metastasize to the lymphatics around the urachus. These tumors should be widely removed together with the paracystic tissues. I say this because I have had such cases in which radium has failed and in which operation has succeeded. Proof enough.

There is another bladder tumor in which total cystectomy is indicated. This is the widely disseminated papilloma or papillary carcinoma. No other treatment can cope with this disease.

As far as my experience goes, all other tumors both papillary and infiltrating are better dealt with by radon implantation. While there may be differences of opinion as to the best treatment of tumors of the lateral walls, I believe that there is little question of the superiority of radon implants in tumors over or near the ureter orifices, the trigone or the internal urethra.

SUMMARY

Bladder cancers both papillary and infiltrating are well adapted for attacks by radon implants.

In 257 cases seen up to and including 1937, 112 were papillary and 145 infiltrating.

Excluding 15 cases, in most of which there were metastases and palliative operation was performed, 56.1 per cent of patients with papillary cancer are well for five years and 28.9 per cent with infiltrating cancers well for five years. Combined there is a five year cure rate of 40.4 per cent.

Both the suprapubic and the cystoscopic route have been used to apply radon seeds, the latter in about one fourth of all cases.

The chief complications of radon implantation are infection and stone formation. These are becoming less with modifications of the original technique of implantation.

Tumors of the bladder vault and extensive papillomatosis are better dealt with by surgery alone. In all other bladder cancers radon implantation is simpler to effect, has a lower operative mortality and gives more assurance of five year cure.

114 East Fifty-Fourth Street

ABSTRACT OF DISCUSSION

DR. GEORGE G. SMITH, Brookline, Mass. I agree in many respects with what Dr. Barringer has said about the use of radium. I have used it for many years. The use of radium has settled down into a fairly well defined groove. Any tumor which is not a perfectly frank, benign papilloma should be treated with radium or resection, in addition to electrocoagulation. I have been disturbed in reading case records submitted by candidates for the Board of Urology to find that radium is used very little. Men often say it would have been a suitable case in which to use radium but the seeds were not available. Of course, they could have been obtained from one of the supply houses if the situation had required their use. I deplore the custom which seems to be quite universally followed, particularly since the introduction of the resectoscope, of resecting a fairly good sized broad based tumor, perhaps a tumor with a base 1 or 2 cm. in diameter, and coagulating the base with the resectoscope, without implanting radon around the base of the tumor. The immediate results have been good, the results a year after have been good, but I wonder what they will be in three or four years. I agree with Dr. Barringer that the case of multiple papillary tumors is the type in which cystectomy is the most valuable method. I have treated some of those patients in which the low grade tumors have recurred time and time again. I have treated them with electrocoagulation and implantation of radon until the bladder has become a small, shrunken, sclerotic organ which bled freely and which in 2 cases had to be removed because of intractable bleeding. In 1 of those cases no tumor was found, in the other not much tumor. I believe that total cystectomy would have been much better in the beginning. Dr. Barringer has said nothing about the use of high voltage roentgen therapy. I am not clear as to how effective it is going to be. Dr. Colby has been much interested in this form of therapy and has treated a number of patients, often with very good results, although I think he feels that

absolute cure is seldom achieved. There is a type of extensive tumor of the bladder in which the area of the bladder involved is so great that I would not want to put radon enough in the tumor to control the growth. In those cases I think one might do a frankly palliative electrocoagulation, might try roentgen treatment, or, if on opening the peritoneum, one finds no evidence of metastases, one might employ total cystectomy, at least relieving the patient of a dirty, sloughing ulcerative bladder. Even if the patient dies from recurrence he is probably going to die more comfortably than he would from carcinoma of the bladder.

DR B S BARRINGER, New York. I have talked to Dr Colby about high voltage roentgen therapy and I think his ideas are sound. He believes that if one has a very large tumor which can't be handled in any other known way, if one subjects that patient to high voltage roentgen therapy the tumor may shrink enough to do something else with it, preferably to implant it with radon seeds either suprapubically or through the cystoscope. I have had quite a number of such cases in which one uses roentgen rays, radon seeds and fulguration, and queerly enough with a certain amount of persistence some of them get well. Not a large percentage, certainly. All in all, however, high voltage roentgen therapy has in bladder tumors a very limited sphere of usefulness.

Clinical Notes, Suggestions and New Instruments

CHRONIC ANEMIA AND LEUKOPENIA IN COMBINED ACETANILID AND AMINOPYRINE POISONING

V THOMAS AUSTIN, M.D., URBANA, ILL.

Acetanilid and aminopyrine are both widely distributed in proprietary nostrums. Each has been shown to produce serious toxic reactions in susceptible persons or under circumstances of excessive dosage. Despite this fact and because they are highly efficient analgesics, tons of these drugs are sold annually to an unsuspecting public. As early as 1886¹ case reports of acetanilid poisoning began to appear in the literature. However, it was not until 1934 that Madison and Squier² presented the initial evidence that aminopyrine in a hypersensitive person produces serious or even fatal neutropenia.

Acute acetanilid poisoning is comparatively uncommon.³ It follows overdosage or in the susceptible person may result from an ordinary therapeutic dose.⁴ The symptoms cyanosis, prostration and collapse may appear within a few hours. A number of deaths have been reported.⁵ Chronic acetanilid poisoning is more frequent than is generally appreciated. Symptoms are not always pronounced, and patients addicted to the use of acetanilid are characteristically secretive regarding its use.⁶ The principal manifestations are cyanosis, anorexia, cachexia, anemia, varied psychic and neurologic disorders, lassitude, insomnia and headache. As headache is often the complaint for which the drug was originally taken, a vicious cycle is established. Splenomegaly occurs occasionally, as was pointed out by Herrick and Irons in 1906.⁷ Tolerant develops, and enormous doses of acetanilid have been taken without immediate untoward effect.³ The insidious aspect of chronic poisoning is the habituation, and it frequently parallels the

degree of tolerance.⁸ Withdrawal symptoms occur and are often alarming. Acute mania may develop, and Payne⁹ has reported a completely quieting effect from as little as 0.3 Gm of acetanilid in such a case. The case reported here is an instance of chronic acetanilid poisoning in which an associated neutropenia may have resulted from a hypersensitive reaction to aminopyrine.

Chart 1—Graphic record of interval blood counts over a nine year period. The crisis in 1941 is better illustrated in chart 2.

REPORT OF CASE

A white woman aged 44, who had been observed at intervals over a period of nine years, complained of headache, lassitude, depression, weakness, anorexia and insomnia. During the first four years these symptoms were intermittent and punctuated by attacks of severe neutropenia, anemia, fever and gingivitis. Temporary improvement would follow hospitalization and intramuscular injections of pentnucleotide. During the next four years the symptoms were more continuous, with progressive loss of weight, dyspnea, palpitation and frequent infections of the upper respiratory tract. Splenomegaly, observed in 1933, became gradually more pronounced. Gingivitis, at first mild and associated with the exacerbations, became chronic and progressive. The early lassitude was followed by inability to concentrate, definite personality changes, carelessness regarding household duties and finally delusions of infidelity regarding her husband. Cyanosis of the lips and mucous membranes appeared intermittently during 1940.

Chart 2—Composite record of the blood picture and rectal temperature during hospitalization.

Throughout her illness, significant changes were present in the blood picture. These are shown graphically in chart 1. The episode of profound neutropenia in 1933 was diagnosed agranulocytic angina, but this did not satisfactorily account for the anemia. After the discovery in 1934² that aminopyrine

was responsible for neutropenia in certain cases she was questioned repeatedly regarding the use of drugs. From 1937 till 1941 her leukocytes were never found to number more than 3,000 and there was a progressive decline in the percentage of neutrophils. Likewise there was a persistent normocytic anemia. Treatment during this period consisted in the administration of iron, intramuscular liver extract and pentnucleotide. It is significant that pentnucleotide was ineffective unless the patient was in the hospital.

During an exacerbation of symptoms in November 1940 the urine was normal. The reticulocyte count was 16.3 per cent, without previous liver therapy. The platelets numbered 246,000. Bleeding and coagulation times were normal. The icterus index was 7. There was an apparent response to intramuscular liver extract with an improved leukocyte count on December 16. A few days later an infection of the upper respiratory tract occurred and she was confined to bed. A tender grape-sized nodule appeared in the left axilla. This gradually diminished in size but previous symptoms became aggravated and on December 31 she was admitted to the hospital.

Chart 2 represents a composite picture of the blood and temperature changes during hospitalization. On admission she appeared to be acutely ill. There was a pallor and cyanosis of the face, mucous membranes and nail beds. She was moderately dyspneic. The heart and lungs were normal and the blood pressure was 130 systolic and 80 diastolic. The gums were inflamed, ulcerated and retracted, and the teeth very loose. The spleen came down 3 fingerbreadths below the costal margin. At this time the hemoglobin measured 33 per cent and there were 2,190,000 erythrocytes and 1,600 leukocytes per cubic millimeter. There were 19 per cent neutrophils. The reticulocytes numbered 20.6 per cent, with an occasional normoblast. A urinalysis gave negative results. The blood urea measured 20 mg per hundred cubic centimeters. On December 31 and again on Jan 2, 1941 she was given transfusions of 500 cc of whole blood. An initial apathy and confusion was followed by an agitated delirium with generalized muscular twitching and almost constant grimacing with sucking movements of the lips. This was followed on January 10 by frequent generalized convulsions with interval coma. The pupils were normal. There was definite nuchal rigidity. The deep reflexes were hyperactive, but the Babinski sign was absent. A lumbar puncture revealed clear fluid under normal pressure with 1 small lymphocyte per cubic millimeter, no globulin, a normal colloidal gold curve and a negative Wassermann reaction. At this time the blood calcium was 10.7 mg per hundred cubic centimeters. The carbon dioxide combining power of the blood during a convulsion was 28 volumes per cent. The next day it was 44 volumes per cent. Dr Israel

Chart 3—Leukopenic response to an oral dose of aminopyrin following recovery.

Davidsohn examined smears of the bone marrow obtained by sternal puncture on January 11. At this time the qualitative picture of the granulocytes was relatively normal, but he found a definite increase in the number of erythroblasts.

The aforementioned nodule in the left axilla was again observed on January 7 to be sensitive, with signs of local cellulitis. This rapidly increased in size and became fluctuant on January 14. At this time it was incised and drained of 1 ounce (30 cc) of thick pus showing many staphylococci on smear and culture. Within several hours the convulsions ceased and the patient became rational. Improvement followed rapidly,

and she was discharged from the hospital on January 22 with a normal blood count.

Shortly after the patient's admission to the hospital it was discovered that she had been taking preparations containing acetanilid and aminopyrine surreptitiously for years. The former was present in Dr James' Miniature Headache Powders, which she had used daily for sixteen years. According to the manufacturers, each powder contains $2\frac{1}{2}$ grains (0.16 Gm) of acetanilid in combination with caffeine and sodium

Chart 4—More pronounced leukopenia following repeated 0.3 Gm oral doses of aminopyrine. This was followed by a rather prolonged neutropenia.

bicarbonate. The latter was present in aminaneon, a combination of 4 grains (0.26 Gm) of aminopyrine and $1\frac{1}{2}$ grains (0.1 Gm) of a barbiturate. For at least nine years the patient had been taking this drug without realizing that it contained aminopyrine. Based solely on her charges at a local drug store it is estimated that during the month of December her average daily consumption was $12\frac{1}{2}$ grains (0.8 Gm) of acetanilid and 12 grains (0.8 Gm) of aminopyrine.

Since leaving the hospital the patient has taken no medicine of any kind. She no longer suffers from headache. Her color is good. She has gained 20 pounds (9 Kg) and she is now cheerful and mentally alert. As seen in chart 1, blood counts had remained normal. The splenomegaly, present for nine years, subsided rapidly, and by February 25, one month after leaving the hospital, the spleen was no longer palpable. However, the teeth remained loose and a full mouth roentgenogram revealed pronounced degeneration of all supporting structures of the teeth. During April Dr Thompson did a complete upper and lower alveolotomy.

COMMENT

There is no doubt that the patient was chronically poisoned with acetanilid, as manifested by the cyanosis, anorexia, cachexia, psychosis, splenomegaly and severe withdrawal symptoms. Likewise the chrome anemia with hyperplasia of the erythropoietic tissues, evidenced by the high reticulocyte count and the bone marrow studies, is typical of acetanilid poisoning. On the other hand, persistent neutropenia with severe crises has not been observed, so far as I have been able to determine. Kracke¹⁰ in 1938 gave an excellent review of the drugs responsible for neutropenic states. In the consideration of acetanilid, he felt that the existing evidence was inadequate. He referred specifically to the cases of Watkins,¹¹ Hudnutt¹² and Groen and Gelderman,¹³ as well as to his observation of neutropenia in a person taking Dr Miles' Nervine. Lowy and Helms¹⁴ observed a mild transitory leukopenia in 5 human subjects given 11 grains (0.7 Gm) of acetanilid daily, six days a week, for from seven to twenty-one weeks. They reported that the blood returned to normal in spite of continued administration of the drug.

It therefore becomes necessary to consider aminopyrine as an agent responsible for neutropenia in this case. The clinical

course is not incompatible with this view. In the nine year record there were periods of neutropenia with only slight anemia. Accurate history is not available, but these may have been periods of greater aminopyrine and diminished acetanilid consumption. Severe episodes of anemia were always accompanied by neutropenia. It is possible that at these times increased consumption of acetanilid occasioned the usual anemia for which greater amounts of aminopyrine were taken. This is substantiated by the patient's history.

In an effort to prove relationships between aminopyrine and neutropenia in this case, tests for specific sensitivity were conducted. A number of investigators¹⁵ have administered test doses of the drug to patients recovered from aminopyrine neutropenia. Varying degrees of neutropenia have been produced. The results of our first experiment are shown in chart 3. In accordance with the proposal of Down,¹⁶ 1 gram (0.065 Gm) of aminopyrine was given by mouth followed by estimations at twenty minute intervals of the total leukocytes and neutrophils. A rather significant drop below the control level was observed in forty minutes, with a rapid return to normal. Next, the patient was given 20 grams (1.3 Gm) of aminopyrine in divided doses over a twenty four hour period. Chart 4 shows the results of this experiment. A more substantial decrease in the leukocytes and neutrophils was observed at the end of this period followed by a return to the previous normal level. This response compares favorably with that in 1 of the 4 cases in which similar tests were given by Dameshek and Colmes¹⁷ in which sensitivity to aminopyrine had been well established. In 2 of their cases a definite neutropenia was observed, while in the fourth no response followed oral administration of the drug.

Finally, following the procedure of Dameshek and Colmes, intradermal tests were made with (1) a 5 per cent solution of aminopyrine, (2) "serumized aminopyrine," prepared by refrigerating a mixture of the patient's serum with 5 per cent aminopyrine and (3) the patient's serum as a control. A definitely positive reaction occurred with "serumized aminopyrine." The other two tests gave negative results. A single control patient gave negative results to all three injections. The positive cutaneous reaction to "serumized aminopyrine" was found by these investigators to be quite specific for aminopyrine hypersensitivity. In 2 of their cases severe neutropenia developed after the intradermal "test." My patient showed no change in the total leukocytes, but it is interesting that after these three procedures the percentage of neutrophils declined from a previous 70 per cent or more to less than 50 per cent. This persisted for four weeks. There was no substantial change in the hemoglobin or erythrocytes.

Should the neutropenia in this case have been due to aminopyrine, as seems likely, it was more chronic and the "anaphylactic" reaction less dramatic than usual. The patient's response to the various tests are in line with this aspect of the clinical course. It does not necessarily follow that these two drugs acted independently of each other to produce the anemia and the leukopenia. It may be that one served as a conditioning factor to alter the toxic effect of the other. Rhoads and Miller¹⁸ have so conditioned dogs by deficient diets that they became seriously anemic when given aminopyrine or crystalline indole, whereas neither diet nor aminopyrine or indole alone was similarly effective. It would have been interesting to test the patient with acetanilid alone. However, this was considered unwise because of the danger of reestablishing habituation.

The cyanosis in chronic acetanilid poisoning is a valuable diagnostic sign, but unfortunately it is not always present. Its mechanism is poorly understood. It seems to be due in part to the presence in the blood of dark colored oxidation products of para-aminophenol and also to the presence of methemoglobin and sulfhemoglobin.¹⁹ Severe neurologic disorders may follow abrupt withdrawal of acetanilid, but convulsions have not been reported in human beings. It is significant, however, that Payne⁹ observed them in one of two dogs in which he studied the abstinence syndrome of acetanilid. Of course, it is possible that in this case the associated neutropenia and sepsis contributed to the convulsions.

SUMMARY AND CONCLUSIONS

In a case of chronic acetanilid poisoning an associated neutropenia appears to be related to aminopyrine hypersensitivity. As far as I can determine, this combination of effect, or possible conditioning action of one drug for the other, with resultant anemia and neutropenia, has not been previously reported.

Addiction to acetanilid may be profound, and the associated psychic changes with secretive self medication may interfere with early diagnosis.

Convulsions following abrupt withdrawal of acetanilid have not been reported in human beings. They might not have occurred in this case had it not been for the associated neutropenia and sepsis.

The progressive inflammatory degeneration of all supporting structures of the teeth is quite unusual and presumably developed on the basis of a persistently lowered leukocytic barrier.

The splenomegaly of chronic acetanilid poisoning though present for years is rapidly reversible.

HANDBOOK OF NUTRITION XIX

THE FEEDING OF HEALTHY INFANTS AND CHILDREN

PHILIP C. JEANS, M.D.

IOWA CITY

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

THE FEEDING OF INFANTS

Human milk commonly is considered the ideal food for the young infant, presumably supplying all nutritional essentials for the early period with the exception of adequate vitamin D. When human milk is not available, cow's milk is the material most commonly used in substitution. It seems desirable to review the comparisons of these two foods as to their contents of various nutritional essentials and their effects on the growth and body composition of the infant. Comparative contents of the two milks are shown in tables 1 and 2.

The protein requirement of the infant commonly is stated on the basis of the average amount received in human milk when he is making good growth progress. The amount of protein received by the young infant under these circumstances is 2 to 2.5 Gm for each kilogram of body weight. Acceptance of the concept,

not clearly proved, that human milk protein is biologically superior to cow's milk protein by a factor approximating 20 per cent makes the requirement of the young infant for cow's milk protein 2.5 to 3 Gm for each kilogram. It is a common practice to supply the young artificially fed infant with at least $1\frac{1}{2}$ ounces of milk for each pound of body weight. This amount is equivalent to 100 cc for each kilogram and a protein intake of 3.4 Gm for each kilogram, an amount in excess of the theoretical requirement as based on the assumed requirement for human milk. Many pediatricians prescribe even larger quantities of milk.

Observations have been made on the effect of ingestion of the larger quantities of cow's milk in comparison with the effects of feeding human milk. In chart 1 are shown the percentages of nitrogen content of infants when they are given these two types of food. After birth the percentage of nitrogen content of babies receiving cow's milk increases in a curve smoothly continuous with the curve of prenatal content¹ and in a manner comparable to the curve predicted by Moulton² for the fat free animal body. On the other hand, when human milk is fed a sharp change in direction of the curve of percentage composition occurs after birth and for a time the proportion of nitrogen in the body remains at the birth level or decreases slightly.¹

Somewhat similarly to the body content of nitrogen, the percentage calcium content of the body differs after birth with human and cow's milk feeding.¹ As shown in chart 2, a decrease occurs with both types of feeding for several weeks after birth, after which period the body content with cow's milk feeding starts to rise, while that with human milk feeding continues to fall for several weeks more and probably does not reach the birth value before the baby is 1 year of age. The calcium of human milk is used more efficiently than that of cow's milk, but the total retention from cow's milk is far greater because of the larger quantity fed. The

calcium retention of the baby fed cow's milk is as great as or greater than the intake of the breast fed baby.

The significance of these various differences in body composition of the infant is not clear. One interpretation could be that a wide range of normal exists and that

these differences are of no significant importance. The period of time during which these differences exist is relatively short compared with the life span. The differences disappear soon after the differences in diet cease to exist. While this point of view may be acceptable for the baby born at term, it seems inappropriate for the baby born prematurely, at least as concerns

calcium. The chief reason the prematurely born baby is highly susceptible to rickets appears to be the low calcium content of the body at birth and the difficulty of supplying sufficient of this material after birth. Human milk cannot be ingested in sufficient amounts to supply the calcium need unless it is fortified or supplemented with calcium or a calcium containing food.

In explanation of the high calcium content of the baby fed cow's milk as compared with the baby fed human milk, and perhaps with the justifiable concept that human milk is the ideal food, the idea has been advanced that the baby fed cow's milk is supermineralized. Eliot and Park³ interpreted the results of their study of the bones of newborn babies as indicating that calcium is present in sufficient amount to represent storage. This interpretation was accepted by Hamilton,⁴ who expressed the belief that the relative calcium loss in early infancy represents utilization of stores and is normal. After 3 months of age the rate of percentage of calcium increase in the body when cow's milk is fed parallels the fetal rate, a condition which, if it does not represent physiologically normal growth, at least produces storage. Storage to this extent certainly is not harmful, and it may well be considered useful during periods of illness when calcium utilization is impaired. The rate of calcium increase after 3 months of age for the baby fed cow's milk is similar to the rate of increase of the ash content of the fat free animal body as predicted by Moulton.⁵

Linear growth of babies fed a standardized cow's milk formula is related to the amount of calcium retained. The differing retentions with the standardized

diet are obtained by varying the vitamin D intake. Babies with poor retentions grow at average or less than average rates, while those with higher retentions grow at rates greater than average. Thus the higher calcium retentions would appear to be definitely advantageous to the artificially fed infant. On the other hand the breast fed baby has excellent linear growth despite the much lower calcium retention and grows at a definitely greater rate than the artificially fed baby with the same calcium retention.⁶ It becomes obvious from these and other facts that factors other than those under consideration enter into the rate of growth and that probably it is inappropriate to state requirement standards for the artificially fed baby based on the requirement of the baby fed human milk.

The greater nitrogen retention of the artificially fed baby must of necessity represent larger amounts of tissue protein in the body, since nitrogen is not stored in any other fashion. The larger part of the increase in tissue protein is represented in increase in muscle mass. Babies who are fed cow's milk in the larger of the customary quantities have approximately 25 per cent more muscle mass than babies breast fed.⁷ This increase takes place soon after artificial feeding is started, after which time the muscle mass maintains a fairly constant relationship to the total body weight. Thus the muscle masses of breast fed and artificially fed babies increase in a parallel manner, but with larger values for those receiving cow's milk. No disadvantage seems to accrue to the breast fed baby because of the lesser amount of muscle. On the other hand nitrogen retentions of the artificially fed baby of the same order of magnitude as those of the breast fed baby are associated with poorer tissue turgor and poorer motor development than are shown by artificially fed babies receiving the larger amounts of cow's milk and having higher nitrogen retentions. If these observations are correct, cow's milk formulas devised to simulate human milk in composition are not as useful as are formulas containing larger amounts of protein and calcium.

The phosphorus content of the body and the phosphorus requirement depend on the amounts of calcium and nitrogen retained. Consequently the requirement of the baby receiving cow's milk is somewhat greater than that of the infant fed human milk. The phosphorus content of human milk is much less than that of cow's milk, but human milk contains an amount sufficient to meet the needs of the infant relative to the amounts of nitrogen and calcium retained. Cow's milk contains an excess to the extent that much more phosphorus is absorbed than can be used, the excess being excreted chiefly in the urine. Little or no phosphorus is excreted in the urine of the breast fed baby, whereas in the artificially fed baby 60 to 70 per cent of the total excretion is by way of the urine. The baby seems to accomplish the increased excretion without difficulty or damage.

Human milk is superior to cow's milk as a source of iron. Though human milk contains only from 0.5 to 1.5 mg of iron to the liter, it contains on the average three times as much as does cow's milk. The iron stores of the body of the baby at birth are sufficient to permit maintenance of a normal hemoglobin level for several months after which time additional iron is necessary. After 3 months of age with customary cow's milk

formulas the iron retention is variable, but averages approximately zero, when human milk is fed, the average retention is approximately 0.11 mg. Neither of these iron intakes is satisfactory, for a retention of at least 0.7 mg is required after 6 months to maintain the hemoglobin level.⁸ Without additions the body of the baby becomes progressively poorer in iron. The iron content of human milk and its utilization are such that nutritional anemia is much slower to develop in the breast fed baby than in the artificially fed baby when no iron supplement is given.

Many times in the past the question has arisen whether the infant needs vitamin A in addition to that present in a customary diet and without the use of any of the fish liver oils. In the light of present knowledge of the requirement of the infant for vitamin A, the Food and Drug Administration has set the minimum requirement at 1,500 units daily and the Food and Nutrition Board of the National Research Council has recommended the same amount as a suitable allowance. For a baby 1 year old this amount is greater than that computed as optimum on the basis of weight from animal experiments when all the vitamin A is ingested as carotene. Thus the amount suggested appears to be ample even if supplied wholly by carotene. Computation shows that the required amount of vitamin A is supplied by milk alone, either human⁹ or bovine,¹⁰ if it is of average content. In the early months the breast fed baby receives more vitamin A than does the baby fed a cow's milk formula prepared by dilution. In addition to the vitamin A of the milk the early addition of orange juice makes a small contribution and the subsequent additions of egg yolk, vegetables and fruits permit an intake of vitamin A well above the requirement. Clinical observations also have shown that babies receiving a normal standard diet grow equally well whether or not they receive additional vitamin A in fish liver oil.¹¹ Thus for the average baby the important contribution of fish liver oil is vitamin D.

The ascorbic acid content of human milk varies directly with the intake of the mother,¹² but in general is relatively large in comparison with the content of prepared cow's milk. An approximate average content of human milk in this country is 60 mg to the quart,¹² whereas a cow's milk formula prepared by boiling and dilution may contain 6 mg or less to the day's supply.¹³

Thus average human milk meets the present standard allowance for vitamin C, whereas the amount in prepared cow's milk is grossly inadequate. Even though the requirement is met by average human milk, the feeding of orange juice to the breast fed baby is in no way harmful and may be considered beneficial in those instances in which the mother's supply of this material is small.

The thiamine content of human milk varies widely and depends on the diet of the mother.¹⁴ According to Knott and her co-workers,¹⁵ milk from mothers able to supply their infants adequately contains more thiamine than milk from mothers whose babies require a formula supplement. The milk of the mothers of babies requiring supplement contained an average of 86 micrograms (29 units) to the quart. When the milk supply of the mother was adequate, the average thiamine content of the milk was 192 micrograms (64 units) to the quart. The larger of these two thiamine contents was observed when the intake of the mothers was approximately 1.5 mg of thiamine daily. When the two groups of mothers were considered together, the average thiamine content of the milk was 144 micrograms (48 units) to the quart. Clements¹⁶ observed symptoms of partial thiamine deficiency in 8 per cent of a group of 150 breast fed infants. The thiamine content of the milk was low in each case.

has stated a probable requirement of 40 micrograms for each kilogram.¹⁸ Though these standards are approached, only the Food and Drug Administration standard is fully attained by average human milk or by the average formula. It is by reason of these facts that questions have arisen as to the adequacy of the thiamine intake of the infant, particularly the breast fed infant. The breast fed infant, though he has no thiamine to spare, seems to do very well nutritionally. One difference between human milk and formulas of cow's milk is the higher proportion of calories from fat in human milk feeding. Slightly more than 50 per cent of the calories of human milk are from fat, while the calories from fat in a customary milk formula often are as low as 35 per cent. Thiamine is not concerned in fat metabolism, and fat consequently has a sparing action on this material. Therefore the thiamine requirement is more equally met in the two instances than seems apparent at first thought. In any case early supplement with thiamine containing foods is desirable.¹⁹

The riboflavin content of milk varies widely for the human being¹⁹ and to a lesser extent for the cow,²⁰ depending on the intake. The average content of cow's milk is approximately five times that of human milk, and the baby's supply from human milk probably reaches only occasionally the minimum standard of 0.5 mg daily set by the Food and Drug Administration or

TABLE 1—Approximate Percentage Composition of Human Milk and Cow's Milk

From Marriott W. M. Infant Nutrition revised by P. O. Jeans. St. Louis: C. V. Mosby Company, 1911.

Cow's milk as fed to babies is subjected to heat treatment, which causes significant losses of thiamine as compared to the original milk. Data concerning the proportion of loss are few and not wholly in agreement.¹⁷ Reference to the values shown in table 2 shows that heat treated cow's milk contains more thiamine than does human milk. However, cow's milk usually is diluted for feeding the young baby. Even with maximum customary dilution, the thiamine intake of the artificially fed baby equals or exceeds that of the breast fed baby when averages are considered.

The Food and Nutrition Board of the National Research Council has set a standard allowance for thiamine at 0.4 mg (133 units) for infancy, the Food and Drug Administration a minimum requirement at 0.25 mg (83 units). These values may be interpreted to indicate a requirement of 40 and 25 micrograms respectively for each kilogram of body weight. Knott

0.6 mg recommended by the Food and Nutrition Board. However, human milk comes much nearer to meeting the stated requirement for riboflavin than it does for thiamine. Applying the same type of discussion as was given for thiamine, it would appear that the average breast fed baby probably is adequately supplied with riboflavin.

Both human and cow's milk are poor sources of nicotinic acid or niacin,²¹ human milk probably being the poorer of the two as with most other members of the vitamin B complex. It is probable that the amount of niacin in milk, at least human milk, is dependent on the intake of the mother. On the basis that the requirement for niacin is approximately ten times that for thiamine, the niacin requirement of the infant may be from 250 to 400 micrograms for each kilogram. Thus the requirement of the young infant, before niacin con-

taining supplements are commonly given, would be from 1 to 2 mg daily. If such a requirement is met, it is only barely met by either human milk or formulas of cow's milk. In the present state of our knowledge early supplement with niacin containing foods seems desirable for all infants.

Neither human nor cow's milk²³ supplies an important amount of vitamin D. The various relationships of the components of human milk, including the calcium to phosphorus ratio, are such that calcium and phosphorus are more efficiently utilized from this food than from cow's milk. It is well known that rickets is less common among breast fed than among artificially fed infants. Nevertheless, breast fed babies sometimes develop rickets and the calcium and phosphorus retentions of babies receiving human milk are increased when vitamin D is given. The requirement of the breast fed baby for vitamin D is not known accurately, but probably it is little or no different from that of the artificially fed baby, as discussed subsequently.

In the preceding discussion certain large differences in body composition between breast fed and artificially fed babies have been mentioned. The significance of these differences to the baby is not clear. Our present knowledge does not seem to warrant the selection of one type of composition as preferable to the others. Detailed nutritional studies have not proved any inferiority of human milk as compared to cow's milk in infant feeding despite the facts that certain essential components are present in small amount and that well managed artificial feeding produces a type of body composition that might seem more desirable from certain theoretical points of view. The usual reasons advanced for preference for the feeding of human milk are trite, though largely correct. These reasons pertain to ease of digestion and low bacterial content of the milk, relative freedom of the infant from infection, infrequency of digestive disturbances, production of good growth and physical status, infrequency of serious illness and relative ease of diet regulation. It may be, as so often is stated, that nature intended human milk for the human infant and cow's milk for the more robust stomach and more rapid growth of the calf. However, nature has not informed us so clearly as to when other foods should be added to the diet and what foods should be given. For answers to these questions we must depend on empirical practice as modified from time to time by scientific observation. That certain food components should be added early seems clear.

SUPPLEMENTS TO THE MILK DIET OF THE INFANT

Vitamin C—Most babies at birth have blood levels of ascorbic acid of at least 0.7 mg and some 1.0 mg or more for each hundred cubic centimeters of blood.²⁴ The blood level decreases promptly and rapidly. By the tenth day the artificially fed baby may be expected to have approximately 0.4 mg for each hundred cubic centimeters of blood, a prescurbic level. By the fourth or fifth day the breast fed baby is receiving ascorbic acid in significant amounts, but in the case of the artificially fed baby the custom of delaying vitamin C administration until the second month is altogether too

common. Orange juice, the most frequently used source, even though started late, is commonly given in amounts much too small to meet the need. The young artificially fed baby has been found to need approximately 20 mg of ascorbic acid daily in addition to the small amount in the formula in order to have a blood value for this material comparable to the lower blood levels of breast fed babies. Thus at least an ounce of orange juice is desirable, beginning in the early days of life. By the time the baby is 3 months old the amount of orange juice given could well be two ounces or even more. In the private practice of pediatricians "intolerance" of orange juice is encountered frequently, but in hospital practice this condition is found most rarely; thus, certain inferences are obvious. From the point of view of digestion, orange juice is little more than a 10 per cent solution of dextrose, a material which should not disturb the alimentary tract of the most delicate infant. Perhaps it is not a coincidence that babies who cannot tolerate orange juice also usually have difficulty

TABLE 2—Approximate Vitamin Content of Human and Cow's Milk

	Values for Each Hundred Grams or Cubic Centimeters					
	Total A I U	D I U	C Mg	Thiamine Mg	Riboflavin Mg	Niacin Mg
Human milk	60-800	0.4-1.0	1.2-10.8	0.002-0.006	0.015-0.038	0.1
Average	200		6.4	0.013	0.04

* After several months storage.

† B. Pantothenic acid cow's milk average 0.20-0.40 mg for each hundred cubic centimeters (Livchjen¹⁷, Jukes¹⁸, T. H. The Distribution of Pantothenic Acid in Certain Products of Natural Origin, J. Nutrition 21: 193-199 [Feb.] 1931). Pyridoxine cow's milk 0.13-0.20 mg for each hundred cubic centimeters (Livchjen¹⁷, Henderson¹⁹, LaVell²⁰, Waisman²¹, and Elvehjem²², C. A. Ibid. 21: 589-598 [June] 1931). Human milk content approximately the same as that of cow's milk (Gyorgy²³, Paul. Quantitative Estimation of Lactoflavin and of Vitamin B₁₂ in Cow Milk and in Human Milk, Proc. Soc. Exper. Biol. & Med. 37: 204-207 [Oct.] 1936). Biotin cow's milk average 0.001-0.004 mg for each hundred cubic centimeters (Lampen²⁴, J. O. Bahler²⁵, G. P. and Peterson²⁶, W. H. J. Nutrition 23: 11-21 [Jan.] 1932; Shull²⁷, G. M. Hutchings²⁸, B. L. and Peterson²⁹, W. H. A Microbiological Assay for Biotin, J. Biol. Chem. 142: 913-920 [Feb.] 1942).

with tomato juice. For those who are intolerant to these food materials, ascorbic acid is widely available in tablet form.

Vitamin D—The need for vitamin D from special sources exists from birth. One good argument favoring the use of milk fortified with vitamin D is that probably no one hesitates to prescribe this type of milk for the earliest formulas, whereas perhaps the majority of physicians wait several weeks or into the second month before prescribing a fish liver oil. Fish liver oils in appropriate amounts may be expected to produce no digestive difficulties at 1 to 2 weeks of age. The condition most to be feared at this early age is lipid pneumonia produced by aspiration of the oil. It is partly for this reason that some physicians use concentrated preparations of vitamin D in preference to cod liver oil. Other and perhaps preferable alternatives exist. Preparations of both vitamin D₂ and D₃ are commercially available in solutions which are freely miscible with the milk formula and offer the advantage of dispersion of the vitamin, in which state it is more efficiently utilized than in the concentrated form.

The requirement for vitamin D has been set at 400 units daily by the Food and Drug Administration, 400 to 800 units is the daily allowance recommended by the Food and Nutrition Board of the National Research Council, 2 teaspoons of minimum standard cod liver

oil (approximately 600 units) is the daily dosage suggested by the Council on Pharmacy and Chemistry of the American Medical Association. No acceptable evidence has been found that a normal infant needs more than 350 units daily for optimum or for maximum calcium utilization when the vitamin D is of no greater concentration than exists in cod liver oil.²⁵ The 2 and 3 teaspoons of cod liver oil commonly prescribed contain as much as 1,800 and 2,700 units respectively when some of the high potency oils are used. Some evidence exists that these larger amounts are detrimental in that appetite decreases after several months of use, with consequent decrease in calcium retention and in growth rate.²⁶ One teaspoon daily of the less potent of the acceptable cod liver oils or $\frac{1}{2}$ teaspoon of the highly potent oils is adequate. If preparations of such concentration as viosterol must be used, a dosage of 4 or 5 drops is preferable to the 10 drops commonly used. The dosage of vitamin D should be considered in terms of units, volumes should be stated only in interpretation to the caretaker of the infant in relation to the specific product to be used.

Cereals—It is the almost universal custom in this country to prescribe cereal as the baby's "first solid food." The age at which cereal is given to infants has varied with different generations of physicians, but at the present time the addition of cereal to the diet at 3 months is a common practice. This current practice finds its counterpart in the time of the Roman Empire. Thus it is an empirical custom, its continuance being based on the clinical impression and belief that babies thrive better when receiving cereal. Among the cereal products listed as suitable for infant feeding are farina preparations, foods which presumably add little to the nutritional value of the infant's diet.

Earlier in this review has been mentioned the importance of supplementing the milk diet of the infant with foods containing iron and thiamine and possibly other members of the vitamin B complex. Whole grain cereals and especially fortified proprietary cereal foods contribute importantly to the satisfaction of these needs. Thus an empirical custom receives support from modern scientific evidence, but only when cereal foods are carefully selected.

It is a custom of a few physicians to defer the feeding of cereals until the second half of the first year and to supply the needed iron and B vitamins from egg yolk, vegetables and fruits. When these foods are given in appropriate quantities the supply of iron and B vitamins is somewhat greater than from whole grain cereals, though not greater than from some of the fortified proprietary foods. Thus among the natural foods the known needs of the infant are supplied better from egg yolk, vegetables and fruits than from whole grain cereals. When these foods are given, the feeding of cereal loses much of its importance and may be deferred until the capacity of the infant increases to the extent that the entire group of foods may be taken comfortably.

OTHER SUPPLEMENTARY FOODS

Some of the food values of egg yolk, vegetables and fruits have been mentioned in the preceding section. Egg yolk is frequently given, preferably cooked, at 3 to 4 months of age, sieved vegetables at 4 to 5 months

and sieved fruits at 4 to 6 months. The giving of a variety of these foods twice a day instead of the usual cereal twice daily not only supplies needed nutrients but helps to accustom the infant to variety in flavors and textures of foods, a goal highly desirable from the point of view of forming good feeding habits.

THE PSYCHOLOGY OF INFANT FEEDING

The psychologic aspects of infant feeding are fully as important as those more obviously nutritional. One of the commonest complaints relating to children brought to the pediatrician is anorexia, usually dependent on training in feeding habits and usually having its origin in infancy. Often the formula prescription of the physician contributes to the onset of the difficulty. A definite volume of food is prescribed, and the conscientious and solicitous parent endeavors to give this exact quantity of formula at each feeding regardless of possible variations in appetite. In this manner rebellion against food may have its beginning. The desirability of variety in texture and flavor has been mentioned. These variations should be introduced early. The child who has had only liquid and sieved foods throughout the first year frequently refuses coarser foods when they are finally offered. At least some of the fruits and vegetables offered should be chopped or mashed rather than sieved after the sixth or seventh month. The continuance of bottle feeding after 1 year of age is not good feeding practice and is usually evidence that other environmental factors probably are faulty.

THE FEEDING OF CHILDREN

The conclusion is reached easily that the diets of our children have improved in many ways over those used in the past. It is clear also that they have not yet improved sufficiently even in those economic levels at which the cost of food is relatively unimportant.

It is customary to attribute increased rate of growth of a population group to improvement in nutrition. Certainly it has been demonstrated that nutrition definitely affects the rate of growth. Whether the cause is nutritional or dependent on some other factor at present unrecognized, studies have shown that young people of this country are taller and heavier than were the children of former years. For example, Meredith has shown that boys living in the United States today are 6 to 8 per cent taller and 12 to 15 per cent heavier than was the case half a century ago. He found the size of boys to be related to economic status, presumably a nutritional relationship. He found also that differences in size were unimportant when related to geographic distribution within the United States.

Other studies have shown that well fed babies and children grow at rates greater than average. The growth data of Kornfeld²⁸ (1929) and of Stuart²⁹ (1934) show a growth rate more rapid than the data of Baldwin³⁰ (1921). Though these differences are greater among infants, they appear also for the child. The assumption seems justified that the increased growth rates are attributable to improved nutrition.

Several approaches exist to the obtaining of evidence that current diets are not satisfactory. One of these

is to point out the frequency of dental caries and the dependence of tooth decay on faulty diet. This field of observation is highly controversial in some respects, but numerous investigators have presented evidence of interrelationship between caries and dietary content. A critical review of the evidence would be too involved and lengthy to permit inclusion here. Various investigators have emphasized the importance in the diet of sugar, calcium, vitamin D, ascorbic acid, fluorine, refined foods and the adequacy of the diet as a whole.³¹ Nearly all investigators in the field will agree to the importance of one or more items of this list in relation to dental caries. All the items relate to nutrition or at least to diet content. Another approach to the determination of the adequacy of the diets of the population is by means of surveys. Such surveys indicate widespread dietary faults which undoubtedly affect nutrition according to the degree of fault. Estimates of the prevalence of nutritional deficiency have been published recently.³²

One nutritional essential commonly deficient in the child's diet is vitamin D. Many children receive an inadequate amount from sunshine in summer and few receive a sufficient amount in winter. While giving vitamin D preparations has become routine in infancy, relatively few mothers realize that this material is important throughout the growth period. Without vitamin D, children vary widely in their ability to utilize calcium and phosphorus, for some the utilization is excellent, for others poor. Since the distinction between these two types of children cannot be made without prolonged and detailed special study for each child, it is appropriate to consider that all children require vitamin D. When the calcium and phosphorus intakes are adequate and appropriate, from 300 to 400 units of vitamin D daily will produce retentions of these minerals ample to satisfy the theoretical requirements for normal growth.³³

Except for special therapeutic purposes, probably no need exists for special preparations of vitamin A to be given in addition to that present in the diet. Evidence is conflicting concerning the frequency of vitamin A deficiency among the children of this country. Certainly vitamin A is relatively abundant in many of our foods, and any reasonably good diet contains ample not only to meet the minimum requirement but for storage. It is clear also that if the diet is fortuitously deficient in vitamin A it is deficient also in many other essentials and that much more is needed than addition of vitamin A alone. It is believed that in a high proportion of instances in which children are found to have clinical evidence of vitamin A deficiency the deficiency is dependent on defects of utilization in greater measure than on dietary deficiency.³⁴ Infections and illnesses produce prompt response in impairment of utilization. In the continued presence of illness large therapeutic doses of vitamin A may be required to supply the need or these large doses may fail to produce a noticeable effect.

Dark adaptation tests have a definite field of usefulness in determining vitamin A status, though this issue

has been clouded greatly by misinterpretation. In dysadaptation from utilization deficiency dependent on illness, subsequent improvement has been attributed to increased proficiency produced by practice in the test because no extra vitamin A had been given. Failures to correlate the test results with dietary intake of vitamin A have been used to condemn the tests when all subjects had adequate intakes and gave test results within the normal range. Uncritical reading of such reports has led to confusion in acceptance of the validity of the tests. That dark adaptation tests have found acceptance in authoritative groups is attested by the fact that the vitamin A standards set up by the Food and Drug Administration and by the Food and Nutrition Board of the National Research Council were based chiefly on the results of adaptation tests.

Much circumstantial evidence exists in recent literature to the effect that thiamine probably is obtained by many children in amounts less than those considered appropriate or optimum.³⁵ It is clear that the remedy for this situation, to the extent that it exists, lies in a better selection of dietary components rather than in the giving of special preparations of thiamine. In general, refined cereal preparations are to be avoided except as they have been "enriched." The lower the economic level, the greater the extent to which the energy need usually is supplied by refined cereal products and sugar, sometimes amounting to 50 per cent or more of the total energy intake. Enriched bread and flour have now become available at all economic levels. Much ado has been made over the increasing consumption of refined sugar, some believing that sugar is harmful per se, but all agreeing that it is too likely to replace foods nutritionally valuable. It is refreshing to find another point of view as presented by Macy.³⁵ It has been her observation that, the better the diet from the nutritional point of view, the less the desire of the child for sugar. She has concluded that the amount of sugar taken voluntarily by a child is an excellent criterion of the adequacy of the diet. As the diet is improved, the voluntary ingestion of sugar decreases. If this observation is correct, the point of attack is not to restrict sugar but to improve the diet by increasing the amounts of nutritionally valuable foods offered.

Thiamine is reputed for its effect on the appetite. An important proportion of the children for whom parents seek medical advice are brought to the physician because of anorexia. In few of these instances is the anorexia correctible by thiamine medication. Though the child may be receiving suboptimal amounts of thiamine and other essentials, the fundamental difficulty lies in the environment and training in feeding habits, these bad habits often having had their origin early in infancy. The correction of these habits has little relationship to thiamine.

Vitamins other than those mentioned need little special discussion. A child who ingests his expected

allowance of milk receives from this source alone most, if not all, of the riboflavin required. For the child who does not receive his quota of milk, the possibility of deficiency not only of riboflavin, but of other essentials as well, is to be considered, and the diet must be supplemented accordingly in a special and expert manner if it is to be complete. Meat, particularly the glandular organs and lean pork, is a good source of the B group of vitamins. If ingested regularly, it is a better source of thiamine and niacin than is milk, though it is a fairly good source of riboflavin, it is inferior to milk in this respect. Eggs contribute importantly to the supply of B vitamins as well as other nutritional essentials and should be included in the diet frequently, preferably daily.

Calcium is the mineral requiring chief attention in childhood, since the other essential minerals are more likely to be present in sufficient amount in most diets. Milk and milk products are our best food source of calcium. In the case of the young child the usual diet, exclusive of milk, contains approximately 0.2 Gm. of calcium, the diet of the older child contains approximately 0.3 Gm. The remainder of the requirement of 1 to 1.5 Gm. is normally supplied by milk. Thus with propriety one may speak of the milk requirement in relationship to the calcium need.

A curve of theoretical requirement for retention of calcium may be constructed by apportioning according to rates of growth at different ages the total accretion of calcium from birth to maturity. When such a curve is constructed, the daily retention requirement is found to decrease from approximately 300 mg. in infancy to a low point of about 180 mg. early in the preschool period, then to increase to about 450 mg. at the beginning of adolescence.³⁶ The efficiency of children in calcium utilization varies widely, but, when vitamin D is given, the range of retention is not great, though always the amount ingested exceeds greatly the amount retained. Discussing the calcium requirement in terms of milk, it has been found that during the early part of the preschool period 1 pint of milk in addition to the usual diet permits retentions adequate to meet the theoretical retention requirement, which is low at this age.³⁷ Very quickly after this time and up to approximately 10 years of age the retention requirement is not met until the quantity of milk is increased to 1½ pints daily. The requirement during adolescence is not known with the same degree of definiteness but probably is the calcium content of 1 quart of milk daily. It seems unwise to place any emphasis on the low requirement in the early preschool period. This period is brief. More is received by the baby immediately preceding this period and more is required subsequently. Milk should not be considered solely as a source of calcium. It contributes most importantly to the protein requirement as well as other essentials. Consequently it seems preferable to advise at least 1½ pints of milk after the period of infancy and up to the age of 10 years. The taking of a full quart of milk throughout this period can be considered as beneficial only provided the larger quantity does not crowd from the diet other essential foods. The fear or belief

that the larger quantity may have this effect is widely prevalent but not too well founded, especially for those children who have normal appetites.

Calcium deficiency, at least in moderate degree, is believed to be widely prevalent in childhood. To whatever degree such a situation exists, it is usually much worse during adolescence. At this age period the requirement is increased and too often the intake not only is not increased but actually is decreased, sometimes because of a desire, especially in girls, to remain slim. It is during the adolescent period particularly that dental caries tends to become rampant, a condition believed by many observers to depend on nutrition and by some observers to depend in part on calcium metabolism.

The custom of prescribing or using calcium salts is widely prevalent. Such salts have a definite field of usefulness under special circumstances, but they have no rightful place in the normal diet. When they are used, they should be carefully chosen for the purpose intended and the dosage should be more nearly adequate than it frequently is. The phosphates of calcium are as well utilized as the same salts in milk. The calcium needs for growth can be satisfied easily by means of these preparations. In order that calcium may be usable for growth, it is necessary that a proportionate amount of phosphorus be available at the same time. The calcium of such salts as calcium lactate and gluconate is utilizable for retention only to the extent that phosphorus is present otherwise in the diet. All diets contain at least a fair amount of phosphorus, but the amount usually is not adequate to permit the best use of the calcium of these salts. The chief objection to the customary use of calcium salts is that they are not food in the usual sense and they are often used as a substitute for milk. It is obvious that calcium salts can be a substitute for milk in only a most restricted sense and that the diet must be supplemented in many additional ways in order to compensate for the absence of milk.

The possibility of protein deficiency in the diets of children has received some, but insufficient, attention. One of the criteria which may be used for estimating the protein content of the body is the creatinine output in the urine. Creatinine excretion is directly proportional to the amount of muscle in the body.³⁸ When children are fed ample protein, the creatinine excretion (consequently the amount of muscle) rises to a constant level for each child, with a narrow range at each age period for a group of children.³⁹ When these values are plotted according to age and in terms of creatinine for each kilogram of body weight, a curve is obtained which may be considered as representing normal conditions as regards creatinine output and muscle mass. Creatinine data collected from the literature, as well as data from this clinic, show that the great majority of children studied have creatinine values below, often considerably below, the theoretically normal curve when they first come under observation. Those with normal values are the exception rather than the rule. In all the instances in which observations have been made the creatinine output increases promptly to the normal level when amounts of protein are fed which are consistent with what are considered standard dietary allowances. It appears that when children receive suboptimum amounts of protein they approach as nearly to the

normal creatinine excretion as their protein intakes permit them. It is of interest also that the weight of the child may be, and in fact usually is, within what is considered the normal range when the low creatinine values are observed. The size or weight of the body is not a criterion for judging protein metabolism.

In meeting the protein requirement, emphasis is to be placed on the value of milk. A quart of milk daily supplies most of the protein need of the young child and half the need at the beginning of adolescence. Such a quantity of milk contributes more protein to the diet than any other single food. When milk is excluded from the diet, the protein requirement of the child can be met only if special and expert supervision is given.

SUMMARY

Despite all our modern knowledge of infant nutrition and all the current refinements of artificial feeding, feeding at the breast of the mother remains an ideal procedure. This is true despite the fact that human milk contains only a bare minimum of most of the nutritional essentials and the fact that the body composition of the breast fed infant departs widely from that which preceded and that which follows, in contrast to the body composition of the artificially fed baby, which maintains more closely a smooth continuance of the fetal and postinfancy curve.

Vitamin D is needed early by all babies, whether breast or artificially fed. Vitamin C is needed early by artificially fed babies and is a harmless safeguard for the breast fed baby. No need for vitamin A from special sources exists. If current custom is in error, it errs in the direction of giving too much vitamin D and too little vitamin C and in not giving either of these materials early enough.

Additional supplementary foods should be given at not later than 4 months of age to both breast and artificially fed babies. One important function of these supplements is to supply iron and vitamins of the B group. Another function is to accustom the baby early to variety in flavor and texture for the promotion of good feeding habits. Anorexia and poor feeding habits, which occur so frequently in older children, often have their origin in feeding mismanagement in infancy.

In a general way we have done reasonably well nutritionally by our babies, but not so well for children past infancy. The nutrition of the child has been improved during the past generation, but not to the extent desirable or possible with present knowledge. Though observers do not agree too well as to the particular nutritional or dietary factors responsible for dental caries, nearly all are of the opinion that one or more dietary components may be responsible, either by lack of those which are essential or by the presence of some considered harmful. On such a basis, dental caries is our most widespread nutritional scourge.

At least three nutritional essentials deserve special emphasis in childhood, viz. vitamin D, protein and calcium. Vitamin D is required throughout the growth period, a fact extensively overlooked. Milk as our only constant good food source of calcium is not taken in sufficient quantity by a large number of children. Protein deficiency is much more common than is generally realized. A diet adequate in protein cannot be arranged fortuitously without the inclusion of milk.

Though thiamine is obtained by a large proportion of children in quantities scarcely meeting their

needs, the remedy lies in better food selection, not in thiamine medication. Enrichment of flour and bread and decreased consumption of sugar should contribute materially to the desired end.

Vitamin A from special sources is not needed by the normal child. A diet fortuitously deficient in vitamin A is deficient also in other respects. The remedy is a better diet, not medication.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
AUSTIN E. SMITH, M.D., Acting Secretary

STANDARDIZATION OF ESTROGENS

The therapeutic standardization of estrogens has until recently been quite unsatisfactory. The main factor contributing to confusion and lack of uniformity has been the dependence on bioassay of the various estrogens in laboratory animals. It has been pointed out repeatedly that animals, even of the same strain, react differently to equal amounts of estrogens and comparisons of potencies of estrogens vary tremendously in the hands of different investigators. In the chapter "Commercial Status of Endocrine Preparations" of *Glandular Physiology and Therapy* an appeal was made that estrogens be assayed directly in the human being in order to standardize properly therapeutic applications of the substance and that such assays be made on the basis of weight of estrogens rather than biologic units.

Increasing numbers of crystalline estrogens are being marketed or prepared in weighed amounts. Noncrystalline preparations, of course, require biologic assay, but these should be performed in parallel with weighed amounts of crystalline estrogens of the same type. It now appears, however, that even weighed amounts of estrogens may not be an accurate index of comparison. These instances would apply to various modifications of the estrogens, such as the ethers, esters or other combinations of inert substances with the active estrogens for the purpose of increasing the estrogenic efficiency. There are already on the market a number of esters of various estrogens, such as estradiol benzoate, estradiol dipropionate and diethylstilbestrol dipropionate. Experimentally a number of other compounds have been made available, such as monomethylether of diethylstilbestrol, diethylstilbestrol dipalmitate and dibenzoate. A recent report by S. C. Freed, W. M. Eisin and J. P. Greenhill, "The Therapeutic Efficiency of Diethylstilbestrol Esters" (*The Journal*, Aug. 22, 1942, p. 1412) suggested that the higher fatty acid esters of diethylstilbestrol are more efficient and desirable than the lower fatty acid esters, it is quite possible that in time other estrogens either natural or synthetic as well as other hormonal substances may be combined with high fatty acids. Under these conditions the simple labeling of such preparations by weight does not give a true index of the activity of the preparations, since the active component of the compounds will have varying concentrations depending of course on the size of the inert molecule. Thus, while 1 mg. of diethylstilbestrol dipropionate may contain approximately 0.6 mg. of diethylstilbestrol, 10 mg. of diethylstilbestrol dipalmitate will contain approximately 0.4 mg. of the active component because of the greater weight of palmitic acid. Similar examples may be obtained with other compounds.

Because of the inadequacy of the current commonly accepted animal biologic assays it will be necessary eventually to assay the compounds for therapeutic standardization by testing in the human being no matter how the preparations are standardized by weight. The factors involved in therapeutic standardization should be reduced to a minimum, in order to do this it appears advisable to label such preparations in terms of weight of the active components. In anticipation of this procedure the Council considers it advisable at this time, before the numerous compounds become available commercially, to propose standardization of these substances on the basis of the amount of active component.

THE PEPPER HEARINGS ON MEDICAL MANPOWER

Immediately following the editorials in this issue of THE JOURNAL appears the report of the hearings before the Pepper Subcommittee on Education and Labor dealing with medical manpower. A preliminary editorial on the subject was published in THE JOURNAL last week. Almost simultaneously with these hearings appeared an editorial in the New York Times, a public statement by Michael M. Davis, a press release by the so-called New York Physicians Forum, a group of some one hundred and thirty physicians in New York City. This group includes among its leaders Drs Ernst P. Boas and Miles Atkinson. Physicians will remember the recent appearance of these two physicians on a forum held in Washington and their insistence on a revolution in the nature of medical practice. Even before the United States entered the war, the prediction was made by many physicians that attempts would occur to utilize the emergency as an excuse for radical changes in the administration of medical services in this country.

In the report of the hearings which follows, attention is called particularly to certain highlights which merit special consideration. Dr. Frank H. Lahey placed before the committee the present status of the Procurement and Assignment Service and indicated some of the difficulties involved in the work which it is conducting. Senator Hill was exceedingly courteous to Dr. Lahey, although somewhat later in the hearings Senator Pepper intimated that Dr. Lahey is merely an automaton or marionette functioning at the behest of the Army and Navy. This will no doubt surprise Dr. Lahey.

Dr. Thomas Parran attempted to state the exact situation as he observed it. Both the Senator and his economist advisers seemed to be much annoyed that Dr. Parran did not adopt the words which they endeavored to put into his mouth.

Paul de Kruif, Ph.D. in bacteriology, indicated that he had not made any personal investigation of the Procurement and Assignment Service or of its work and that he was speaking largely from hearsay. He did draw into the situation the case of Dr. Tom Spies. Immediately following the publicity accorded to this incident, the editor of THE JOURNAL called Dr. Spies on the telephone. According to what Dr. Spies reported, it was the belief of a friend and preceptor that Dr. Spies should be in military service, apparently this friend asked de Kruif to speak to Dr. Spies on the subject. This was the widely publicized incident which de Kruif characterized by saying that the American Medical Association had "put the finger" on Dr. Spies. The evidence indicates that de Kruif is dissatisfied with the American Medical Association or those whom he characterizes as its leaders, although the specific cause of his annoyance is not made clear.

Mr. Henry J. Kaiser and the director of his medical services, Dr. Sidney Garfield, claim to have had some difficulties with the local representatives of the Procurement and Assignment Service because of their desire to hold in their permanent organization young physicians who have been marked "available" by the Procurement and Assignment Service.

Senator Pepper did not permit the editor of THE JOURNAL to make any formal statement. The hearing was conducted wholly by the question and answer technique. This procedure Senator Pepper followed frequently with all who appeared, so that much of the hearing is devoted to long statements by Senator Pepper with the answer "Yes, sir" and "Certainly, sir" from those who were supporting the cause in which the hearings were held. The editor of THE JOURNAL apparently found it difficult to say "Yes, sir", it will be observed that he frequently said "No, sir".

Dr. E. J. O'Brien of Detroit, by his own statement hastily summoned to appear, on the suggestion of de Kruif, participated in the tuberculosis campaign in Detroit. Most amazing in his testimony is his statement that he would not oppose a totalitarian government if it could eliminate tuberculosis.

Mr. Michael M. Davis, Ph.D. presumably in economics, spoke as was expected.

It will be interesting to see what kind of report the Subcommittee on Education and Labor makes to its full committee. There is apparently an effort on the part of this senatorial group to set up an independent agency for the control of all manpower, with Mr. Henry Wallace, vice president of the United States, as its head. Presumably they would take authority from the Selective Service System and from the present War Manpower Commission as now constituted and make all agencies subservient to what Senator Pepper calls an "over-all" committee.

THE RENAL PRESSOR SYSTEM

The part played by humoral agents in the genesis of experimental renal hypertension is of profound interest to investigator and clinician. The cycle starts with renin, a heat labile protein present in normal kidneys the existence and properties of which were first described in 1898. Interest in renin revived with Goldblatt's experimental production of renal hypertension. In attempting its purification from the other proteins of the renal cortex, workers in Indianapolis¹ found that the fractions, as they were successively purified, had less and, finally, no vasoconstrictor action on the blood vessels of isolated organs (dog's tail, rabbit's ear) perfused with isotonic solution of three chlorides, although they became more and more effective as pressor agents when injected intravenously into intact animals. The puzzle was solved by the observation that addition of blood or plasma or of a protein fraction from plasma to renin as it perfused isolated vessels resulted in prompt vasoconstriction. It was concluded that renin was not in itself vasoactive but that it became active only when in contact with a substance present in plasma which, pending its identification, was tentatively called renin activator.

At about the same time workers in Buenos Aires demonstrated the presence of a pressor and vasoconstrictor substance in the renal venous blood of dogs during experimental renal hypertension. They found a substance with similar characteristics in the renal venous effluent of dogs whose kidneys had been rendered acutely ischemic². They had gone on to the preparation of extracts of such blood and established in it the presence of a heat stable pressor material, evidently not renin, which they termed hypertensine³. They also came to the conclusion that renin was of itself vasoinactive but that it acted on plasma to liberate this vasoconstrictor.

Meanwhile in this country further studies on the interaction of renin and renin activator had established the enzymatic character of the reaction of the two proteins and formation of a heat stable pressor and vasoconstrictor in the reaction which was called angiotonin⁴. The preparation and general properties of angiotonin and its probable participation in renal

hypertension and the general characteristics of hypertensine were, it appears, reported respectively in Chicago and Buenos Aires within the same twenty-four or forty-eight hour period in November 1939. Since the properties of the substances seemed quite similar, it appeared that workers separated by thousands of miles and by altogether different points of attack had reached simultaneously much the same conclusions.

The interaction was further studied in both countries⁵. In Argentina investigators concluded that renin acted as an enzyme on a protein substrate, called by them hypertensinogen and equivalent to renin activator. Since, however, neither renin nor its proposed substrate was available in pure form, conclusive evidence on this point did not appear. The indications of such activity are evident from the data of both groups. Page and his co-workers therefore provisionally retained the name renin activator in spite of a tendency in biology to restrict the term "activator" to a subsidiary catalyst of enzymatic action.

In the original description of the action of renal extracts containing renin on renin activator, it was shown not only that such extracts caused liberation of angiotonin but that they went on to destroy it⁴. The conclusion that this destruction or inactivation was due to renin itself⁶ was revised, as it was shown both in Argentina⁷ and in the United States that normal kidneys as

well as other tissues contain a substance or substances capable of destroying or inactivating the pressor agent (angiotonin, hypertensine). This effect of tissue extracts was attributed in Argentina to a specific enzyme system, termed hypertensinase, although, lacking full purification of either proposed enzyme or substrate, the evidence was incomplete.

The Indianapolis workers,⁸ cooperatively with Harrison, Grollman and Williams,⁹ had meanwhile described the preparation of renal extracts which, injected into experimentally hypertensive animals or into human beings suffering from essential or malignant hypertension, result in decreased arterial and objective amelioration of many of the subjective and objective manifestations of the disease. They have since brought

GRADUATE TRAINING OFFERED

The Council on Medical Education and Hospitals of the American Medical Association is anxious to be of assistance to physicians who, because of the war emergency, desire additional training or postgraduate courses as a preparation for the assumption of new or added responsibilities in civilian practice.

Any physicians desiring assistance in connection with such programs are invited to communicate with the Secretary of the Council.

forward further evidence on this point¹⁰ While reserving final judgment on the nature of the action of these extracts in vivo, they have tentatively proposed the view that it may be ascribed to the antihypertensin (hypertensinase, angiotonin inhibitor) activity of the extracts as demonstrated in vitro. Wide variations in the severity of hypertension in both experimental and clinical subjects and varying impurities of the extracts have to the present prevented complete correlation of antipressor and antihypertensin effects.

There is thus presented a cycle of entirely independent work leading from different logical approaches to much the same visualization of the role of the kidney as an endocrine organ. The differences in conclusions and points of view of the two groups are largely those of terminology and not of precedence. The terminology of Houssay and his co-workers,¹¹ in which renin the enzyme acts on hypertensinogen the substrate to liberate hypertensin the vasoconstrictor, which may be destroyed by hypertensinase, has a clarifying unity which, in a sense, is lacking to the parallel succession of renin, renin activator, angiotonin and angiotonin inhibitor. If the Argentine terminology is to be criticized, it is largely on grounds, familiar to North American practice, that the term hypertensin implies a participation in hypertension and an effectiveness in hypotension for which little evidence has been advanced, a petitio principii not involved in the term angiotonin. Similarly, lack of knowledge as to the chemical nature of the renin substrate¹² (hypertensinogen, renin activator) as well as of the identity or even the unity of the pressor destroying material (angiotonin inhibitor, hypertensinase) suggests the need of care lest a descriptive but necessarily tentative nomenclature become arbitrarily fixed, and concepts as yet incompletely established become too readily accepted as the equivalent of thoroughgoing demonstration. Since even the renin substrate (renin activator, hypertensinogen) now appears to be formed in the liver,¹³ it may be that even the term "renal pressor system" must eventually give way.

Whatever the ultimate significance of the renal pressor system in the genesis of clinical hypertension, such similarity in conclusions as has been reached by the groups in Argentina and in North America makes their paralleling evidence more satisfying than it could otherwise have been.

IMMUNITY TO TRICHINOSIS

The fact that micro-organisms may undergo an antigenic mutation during the course of natural infections was first conclusively demonstrated with the spirochetes of relapsing fever. Aristowsky and Wainstein,¹ for example, showed that vaccination of human beings with heat killed initial phase *Borrelia recurrentis* protects against subsequent experimental inoculations with the same initial phase of the living organism but does not confer immunity against inoculation with the first recurrent phase of the same infectious agent. Furthermore, these Soviet investigators showed that each relapse during the natural course of relapsing fever is of a new and generally different biochemical specificity. In some instances, however, a relapse may be a reversion to a previous antigenic type. Indeed, similar antigenic mutations have been suspected though not yet proved for the tubercle bacillus.²

The theoretical basis for antigenic mutations has been studied in greatest detail in connection with the "dissociation" of the pneumococcus. As long ago as 1931 Dawson and Sir³ for example showed that under certain test tube conditions type pneumococci may lose their power of synthesizing their original type specific capsular polysaccharide and may acquire or develop then latent power to synthesize capsular polysaccharides of a wholly new type.

This dual nature or double antigenic phase also has been demonstrated by Oliver-Gonzalez⁴ for *Trichinella spiralis* by in vitro tests employing immune serum obtained from rats, guinea pigs or rabbits given larval feedings and mixing with 1 drop of saline worm suspension on a hollow ground slide. The slide was then covered with a sterile cover slip and sealed with petrolatum. After one hour's incubation a fine granular precipitate appeared in the mixture, with coarser and thicker semigelatinous precipitate forming around the anterior end of the worms. During the first twenty-four hours the larvae were able to release themselves from this oral precipitate, but thereafter they became less active and the gelatinous oral precipitate remained attached to them and increased in size. The serum of rabbits artificially immunized by intravenous injections of saline suspensions of powdered larvae had a similar or even more definite in vitro action on trichina larvae but little or no effect on adult worms. These observations seem to indicate that there are antibodies in the serum of naturally hyperimmune animals not formed in rabbits artificially immunized with larval material. The apparent explanation is that the larval and adult forms of *Trichinella spiralis* are of different immuno-

12 Since this editorial was prepared Plentl and Page (Central Soc. Clin. Res. 15: 32 [Nov. 7] 1942) have identified electrophoretically renin substrate (renin activator, hypertensinogen, prehypertensin) with the α globulin fraction of plasma protein. The name of the chemical entity α globulin might well therefore replace the varied descriptive terms previously used.

chemical specificities "Hyperimmune" serums, however, contain both antitubercular and antiadult antibodies. This explanation has been confirmed by fractional adsorption of "hyperimmune" serum with dried larval material, after which procedure the serum possesses only antitubercular immune properties.

The stimulation of two different types of specific antibodies by *Typhimella spiralis* may be considered established. The chemical nature of the dual antigens, however, has not yet been clarified nor have parallel tests of skin sensitivity thus far been made. These are among the pressing problems awaiting further investigation.

Current Comment

MEDICAL LICENSURE FOR "DISLOCATED" PHYSICIANS

Some thousands of physicians have already indicated to the Procurement and Assignment Service for Physicians, Dentists and Veterinarians their willingness to be "dislocated" for the duration of the emergency to meet the needs of the civilian population in some areas from which physicians have gone to join the armed forces. When the proposal was made to accelerate medical education in order to aid the provision of additional physicians at the earliest possible time, the Federation of State Licensing Boards, utilizing the Bureau of Legal Medicine of the American Medical Association, made a survey of the laws regulating the licensing of physicians in various states, with a view to adopting at the earliest possible moment means for modification of regulations or of laws to meet the speeded process of education. If a physician is to be "dislocated" from one area to another in the same state, there will not be any difficulty in licensure. If, however, a physician is to remove to another state in which he has not been licensed, there may be difficulties with securing for him the right to practice. Clearly the processes of licensure must be geared to meet this emergency. No doubt much can be done administratively to meet the situation. The granting of temporary permits to practice for the period of the emergency and perhaps for a brief time thereafter has been suggested as one means of meeting the problem. Already a bill authorizing the issuance of such permits for the District of Columbia is pending in the Congress. In one state, New Hampshire, an amendment was enacted fifteen years ago to the section of the medical practice act prescribing qualifications to be possessed by applicants and authorizing the board of examiners to suspend the requirements in whole or in part in case of war or other threatened or existing national calamity. In this period of war, powers rest in the hands of government leaders the exact limits of which are not fully determined. It has been reported that the Attorney General of the United States has ventured the opinion that licensure laws might be invalidated for the period of the emergency. The suggestion has also been made that state legislatures might immediately pass enabling legislation for

such invalidation if necessary to permit physicians to practice temporarily in such states. The legislatures of forty-four states will meet next year so that the necessity of additional legislation might well be considered at this time. Consideration might be given also to the possibility of eliminating fees for reciprocity in the case of a physician who offers himself for "dislocation" during the emergency. In many states the boards may now grant temporary permits to practice previous to the time of the next available examination. If temporary permits are to be issued, the state boards of registration and licensure will need to establish safeguards to prevent the process from becoming the medium by which standards of medical licensure and practice may be depreciated. As is apparent from the hearings on medical manpower before the Pepper committee, some agencies are not adverse to promoting a revolution in the control of medical practice on the basis of shortages of physicians existing in various portions of the country. Already several efforts have been attempted to break down the standards of medical education and medical care and to bring into the practice of medicine half-educated physicians and incompetent cultists. The Federation of State Medical Licensing Boards should realize that there rests on them at this time a great responsibility. The present requirements on licensure should not be permitted to interfere with the supplying of essential scientific medical care to the civilian population in this period of emergency. Neither should there be tolerated any attempt to break down the high standards of medical education and practice achieved by a continuous struggle of more than thirty-five years.

RADIO BROADCASTS "DOCTORS AT WAR"

On page 972 of this issue appears an announcement of a new series of radio broadcasts by the American Medical Association and the National Broadcasting Company in cooperation with the medical departments of the United States Army and the United States Navy. The series will be entitled "Doctors at War" and will constitute book III of the highly successful "Doctors at Work" broadcasts inaugurated two years ago. This will be the eighth series of dramatized network broadcasts by the American Medical Association and the National Broadcasting Company. The broadcasts will be devoted to three principal purposes: portrayal of the medical care and supervision of the armed forces and the part which doctors play in this important feature of military training and service, interpretation of the medical aspects of maintaining industrial health and production for war, and explanation of important civilian health problems, especially with relation to judicious use of reduced medical facilities. The dramatic method with full use of sound effects and music will be used. The story of fictitious but typical Dr. Tom Riggs and Dr. Paul Gerard and their families, patients, friends and military associates will be carried forward. Subject to war time exigencies, the program is planned to run twenty-six weeks. As heretofore, this is a sustaining program, no radio station derives any revenue from broadcasting it. Time on the network and

on local stations is given gratis as a part of radio's contribution to public service, and the scientific contribution of the American Medical Association to the program is made in the same spirit. Production costs are shared by the National Broadcasting Company and the American Medical Association. Because this is a sustaining program it may face competition on the schedules of local stations with revenue producing features. The National Broadcasting Company does not guarantee the broadcast locally of sustaining programs except over its own stations, yet from seventy to a hundred stations have customarily broadcast the American Medical Association programs. Evidence of local interest in the program on the part of medical societies, auxiliaries, health departments, schools and voluntary health and civic agencies if submitted to the radio station well in advance may result in local broadcasting of the program when otherwise this might not occur. If there are schedule conflicts on local stations, the following suggestions have sometimes resulted in eliminating such conflicts: (a) sponsors of local programs in conflict with Doctors at War may be induced to accept a change of schedule if equally good time can be procured for them, (b) the program may be recorded and broadcast at another available time on the local station schedules.

SNAPSHOTS OF DEATH

The Division of Vital Statistics of the Bureau of the Census has recently initiated a new series of mortality summaries¹ which supply an amazing amount of interesting and significant information. For comparative purposes the mortality figures since 1933 are of more value than those of earlier years, since it was in 1933 that Texas became the final state to enter the registration area. The number of annual deaths of males is higher than that of females in every age group up to that of 75 years and over, when the reverse is true. In 1940 New Hampshire had a death rate from diphtheria of 0.2 per hundred thousand of enumerated population, this was one death for the entire state that year.¹ The deaths from tuberculosis of all forms in 1940 was 36.6 per hundred thousand among white persons and 123.5 among Negroes, it was 33.7 and 112.7 respectively for tuberculosis of the respiratory system. In the same year the death rate from syphilis was 9.9 among white persons and 55.1 among Negroes. However, from cancer of all forms the death rate in 1940 was 125.0 among white persons and only 78.4 among Negroes. Although the death rate from "dysentery" for the United States as a whole was only 1.9 per hundred thousand in 1940, it was 10.1 in Texas and 14.1 in New Mexico. With a death rate for the United States from malaria of 1.1, that for Arkansas was 9.1, for Alabama 7.3, for South Carolina 6.2 and for Florida 5.1. These data illustrate the wealth of information available and the ease with which such statistical data can be used to clarify those health problems of age, racial, local or other groupings which most need attention.

EPIDEMIOLOGY OF GONORRHEA AND THE NAVY

If 8,569 cases of diphtheria or any other acute epidemic disease had been reported as occurring in the 149,618 average population of the United States Navy during 1939, the resulting reverberations would have been nationwide. This number of cases of gonorrhea actually did occur, according to Stephenson and Lang¹ of the United States Navy Medical Corps without producing a ripple of public furor. For approximately thirty years, they say, gonorrhea has consistently remained either in first or in second place among the leading causes of morbidity in the Navy. To learn something of the epidemiology of gonorrhea in the naval service, a ten year unpublished study of this disease has recently been made by Lang.² Some of his observations were that the overall admission rate for the entire navy was 60.61 per thousand, the ten year admission rate for all forces ashore was 37.92 per thousand and for all forces afloat 79.8 per thousand. In the forces stationed within the continental limits of the United States there was a ten year rate of only 31.78 per thousand as compared with a rate of 57.65 per thousand for those stationed ashore outside the continental limits, the ten year rate for the forces afloat within the continental waters of the United States did not differ significantly one from the other, but the ten year rates for forces afloat in foreign waters were astonishingly higher, the highest being attained in the Asiatic Fleet, where it reached 148.41 per thousand. In a special service squadron stationed in the Caribbean waters it was 104.76 per thousand, while in the European Squadron, in two years of experience, the rate was 142.13 per thousand. The history of venereal disease control in the Navy shows a series of steps, many of which were established on a trial and error basis. The program as it exists today is the aggregate of the most successful of these steps. The policy of attempting to control venereal disease by rigid and severe disciplinary measures has been tried and abandoned as not accomplishing its purposes. Under existing regulations, naval medical officers are now required (1) to acquaint all persons in the naval service regarding the nature and dangers of venereal disease, (2) to provide prophylaxis for venereal disease and (3) to give prompt and adequate treatment to all who develop a venereal disease. Stephenson and Lang conclude that one of the major steps in an epidemiologic approach to this disease is cooperation of all competent organizations to assist the authorities in dealing with commercialized prostitution. Today, they say, there is urgent need for more vigorous nationwide intensification of the organized social hygiene program to reduce the morbidity from gonorrhea. With the personnel of all the armed forces of the United States increasing at almost astronomical rates, the epidemiologic importance of controlling venereal disease in the civilian population cannot be over-emphasized.

U. S. SENATE COMMITTEE ON EDUCATION AND LABOR

REPORT OF HEARINGS HELD BEFORE A SUBCOMMITTEE OF WHICH
SENATOR CLAUDE PEPPER IS CHAIRMAN

In addition to Senator Pepper, the members of the subcommittee are Senator Lister Hill (Democrat), Alabama, Senator H. H. Schwartz (Democrat), Wyoming, Senator Robert M. La Follette Jr. (Progressive), Wisconsin, Senator Eugene D. Millikin (Republican), Colorado

NOVEMBER 2, 1942

Present Senators Pepper and Lister Hill, also Robert K. Lamb and F. P. Weber, special assistants to the committee

STATEMENT OF DR. FRANK H. LAHEY,
Chairman, Central Board of Procurement and Assignment
accompanied by

COMMANDER MAXWELL E. LAPHAM,
United States Navy

Senator Pepper Doctor, if you will state your full name and connection, and then give any statement you care to make on this whole subject of manpower, public health, or the doctor angle of the situation, we will thank you very much.

Dr. Lahey I am Dr. Frank H. Lahey, Chairman of the Central Board of Procurement and Assignment.

Senator Pepper What are the duties of the agency of which you are the chairman? *Dr. Lahey* We all had the feeling, all who participated in the last war, that the obtaining of doctors then was on such a helter-skelter method that there were certain areas of depletion. In addition to that we had known the English experience in meeting the needs of the armed forces and we knew that they had arrived at a quota system plan in order to preserve their limited number of doctors. The National Committee on Medical Preparedness met to discuss this problem. I happened at that time to be the President of the American Medical Association. It suggested that to avoid depletion and to be able to obtain an adequate number of doctors for the armed forces and still be able to retain enough for industry, hospitals and civilian population, it would require some over-all program or plan for obtaining and distributing them. By a letter from the President, an Executive Order, this board was appointed and I was appointed chairman. Dr. James Paulin of Atlanta, Dr. Harvey B. Stone of Baltimore, Dr. Willard Camalier of Washington (representing the dentists) and Dr. Harold Diehl of Minneapolis were appointed members.

Previous to the establishment of this plan the American Medical Association, through its Committee on Medical Preparedness, had foreseen the possibility of war. They established a national roster of physicians at their own expense. They had all the doctors of the United States tabulated as to their training, age and so forth. Then came the appointment of this committee and it was turned over to them. Then a second questionnaire went out, 250,000 of those went out to doctors, dentists and veterinarians.

In those questionnaires the doctors were given four choices: 1. Will you go in the Navy? 2. Will you go in the Army? 3. Will you be dislocated elsewhere? 4. Do you wish to remain where you are and participate in the war through your efforts where you are? They answered, the answers have been tabulated, so we know what their preferences are.

In order that we might be certain that we had viewed the situation as an all-over picture, quotas were established for the various states. In establishing these quotas weight was given to the fact that there are more doctors in New York than there are in the rural communities of your state, Senator Hill, of which I happen to know, having spent some of my life there. Dividing the population into suburban and urban, the quotas were weighted to counterbalance, as near as possible, the needs, and these quotas were established for each state. The quotas have been overmet in some states and undermet in others.

By the directive order and by the request of medicine this has been done on a voluntary basis. The Procurement and Assignment Service possesses now no compulsory power either to compel a man to enter the service or to compel him to remain where he is placed. But Procurement and Assignment Service set its organization up on what seemed to me a quite ideally democratic basis. It appointed a chairman for each corps area and with it advisory committees, under that a state chairman

and under that district or county committees in order to establish essentiality and availability. Essentiality for a medical school means how many do they need to run a medical school? How many do they need to run a hospital? How many does a given community need?

The country was divided, in terms of its doctors, dentists and veterinarians, into available and essential. The Army has been interested in men 45 or under, literally 37 years of age or under with troops. They have said that for troops they would like men 37 years or under and for specialists they would like those between 37 and 45 years of age.

We really had the situation quite well in hand as I think I can show you. While we possessed no authority, we could acquire it through the Selective Service.

We sent a letter to every doctor who had signified his willingness to serve, in which was roughly this statement: "You are within the draft age, you have signified your willingness to serve, in a questionnaire, you have been investigated by Procurement and Assignment and you have been found available, nonessential, to your community, medical school and hospital. You are therefore directed to seek a commission."

At the same time Selective Service headquarters in a state was notified to this effect: "This man (John Smith) has signified his willingness to serve, he has been found available, he is within the draft age. This information is given to you to decide whether or not you desire reclassification of this individual." On May 16 a directive had been issued from General Hershey's headquarters which said that any medical officer because he obtains a commission has sufficient income so that he may not claim exemption on the basis of dependency. That gave us a good deal of authority, it seemed to us. This isn't critical, I have to state the facts—immediately on the action of Congress that a man who was married did not come under this head, as soon as the men for instance who were found available, who were single, who were not necessary, we had no authority over them.

In the same way we have no authority if we say to a man, "You are in an area which is being depleted, we think you ought to stay"—if he says, "I won't," we can do nothing about it. Yet on the other hand we realize that sometimes—

Senator Pepper (interposing) Now the Army that takes him of course could do something about it, couldn't they, or the Navy? *Commander Lapham* The Army and the Navy I think have cooperated very well in that respect.

Senator Pepper Suppose a man has presented himself from some area where there was a shortage of doctors already, is he allowed by the Army or the Navy to get a commission? *Commander Lapham* No, sir, he would not be commissioned unless he had been cleared through the Procurement and Assignment Service.

Dr. Lahey He means that if we marked him "essential," the Army wouldn't take him.

Senator Hill You mean essential in carrying out the private practice in that community? *Commander Lapham* Yes, sir.

Dr. Lahey In providing adequate care for that community.

Senator Pepper Is it a fact, for instance that in the state of South Carolina there is a vast coverage in the number of doctors that they have contributed in excess of their quota? *Commander Lapham* That is right.

Senator Pepper How did that happen? *Commander Lapham* South Carolina has—*Senator Pepper* (interposing) Do you have the quotas there, and would you think it proper that they be put in the record? If it is proper I would like to have them in the record, wouldn't you think so, Senator Hill?

Senator Hill As I recall it, the state of Oklahoma is 160 per cent. *Commander Lapham* South Carolina is 170 per cent. *Dr. Lahey* New Mexico is 224. *Commander Lapham* Alabama is 194 per cent.

Senator Pepper What about Florida? *Commander Lapham* Florida has supplied 115 per cent of its quota.

Dr. Lahey You might be interested in knowing how difficult it is to prevent a man from going into the service. I have just read a paper on the subject before the Interstate Post-Graduate Assembly in Chicago, last Wednesday. The man has everything to make him go in the service. He has his standing in the community, he has the pressure of the community, and

there is something you don't think of, he has the pressure of his wife who in turn has the pressure of the wife whose husband has already gone into the service.

Besides that he has another thing that you don't think of, and he has the right, it seems to me, to consider it. He has to consider where he will be when the war is over in terms of the man who is gone and the man who is not gone, because I went through the last war and I know what the reaction is.

After all, you can talk about it but within the medical societies and the inner sanctums where some of the decisions are made, the division has been made into who served and who did not—and he knows that!

So after all, even though we tell him to stay, and even though he knows that the community goes on, sometimes his patriotism—and I mean pure, unadulterated patriotism—and even personal interest, prompts him to do it.

Senator Pepper Which indicates what may be the difficulty, if not the injustice, of making it a matter of personal decision as to whether he shall be in the service or out of it?

Dr Lahey Senator Pepper, if there were some way by which—and you and I know that it is about the only way that you could really make it stick—if there were some way whereby the responsibility for the decision could be taken off the man or even if it could be lessened to a degree where I could say to a man—and this too is in the paper—if I could say to a man, 'You have to do this, but here is a uniform and you are on detached service without pay until you are no longer essential which saves you from saying to everybody who raises his eyebrows at you, "This is the reason I am not in the service"' that would be very helpful. You could give him a button—we have talked about that—but there are so many buttons that no one would know what it was and if you have a button you have to explain what it is and if you have a certificate you have to get it out and unfold it and then ask somebody to read it.

Senator Hill Doctor, the very statement you made is one reason that I have been so strong for a National Service Act. I think we will all agree that every person ought to serve in the place where that person is most needed and can make the greatest contribution to the war effort. Yet for one hundred and fifty years in this country we have thought of a war effort in terms of an Army and Navy, and naturally the urge of patriotism drives men, and drives public sentiment to drive men, to the Army and the Navy.

A National Service Act which would mean a total mobilization of all of our people men and women—under such an Act the Government would make the decision, the Government would make this determination.

The Government would say to Mr. Smith, "You can make your greatest contribution in the Army, we will take you in the Army." "Mr. Jones, you can make your greatest contribution by remaining home and dealing with the medical needs of your community therefore, you stay at home."

Dr Lahey That would relieve us of being in the paradoxical position of saying, "You go," and "You stay," and from being in the paradoxical position of saying that you shouldn't deplete the states.

Senator Hill And the truth of the business is this, that up to date—

Dr Lahey (interposing) They have done pretty well on the whole.

Senator Hill (continuing) —up to date, although you have done pretty well, you haven't been able to say that you can't go to any one?

Dr Lahey We haven't been able to do that at all.

Senator Hill As you say, these figures here show Alabama—194 per cent New Mexico I believe you said was 224—I know of a county in my state of Alabama where before this war came they had seven doctors, practitioners. Today, outside of the county health officer, and of course he is not a practitioner, they have only one practitioner in that entire county—and most of them are either in the Army or the Navy, under the urge of patriotism. Those men have gone, but some of them should have been designated to remain at home and carry on their work.

Dr Lahey I know the Procurement and Assignment Service has made lots of mistakes. I would not for anything have you think that we think it is perfect, it is far from it. After all, here has been a very urgent problem, done quickly, requiring a set-up and lots of things. But the one thing I would like to get before you clearly is that on the whole medicine has done pretty well, it has met the demands. But I should say that the greatest criticism of it has been that it has been uneven in the participation as to states.

Senator Hill But as you say, it did not lay within your power to bring about that evenness? *Dr Lahey* I think 65,000 doctors were under 45 years of age. We had it pretty

well in line as long as we had the pressure of Selective Service on them, and until they could fall back on the fact that a married man did not come under this—we had them pretty well up to that time. In fact, we all sat around and thought that our headache was pretty much over when we sent this letter out directing them to seek commissions and asking Selective Service to reclassify them.

Senator Hill What was the date of that letter, Doctor? *Commander Lapham* That was in May, sometime.

Dr Lahey It was almost at the same time that the directive came out from Congress.

Senator Pepper Have you got into the service most of the doctors who are not married, under 45? *Dr Lahey* Yes, we have got most of them. There are still the states that have not met their quotas—California, Illinois, Pennsylvania, New York and Massachusetts. There are still a number of doctors in those states who are single, available who haven't gone, as a result of which pressure will be put on institutions, medical schools and hospitals in other states who have met their quotas, in order to meet the Army, Navy and Aviation demands.

Senator Hill It is true that a man under 45 years of age is subject to draft, and when inducted into service they could be detailed to do medical work. *Dr Lahey* You wouldn't have to worry about that. It would probably do them good to get two or three months of drilling, and then they would be taken out and put into medicine.

Senator Hill I should think they would be put in almost immediately. *Dr Lahey* I don't have any doubt about that.

Senator Pepper Is that the reason those states are behind in their contribution? Because there happen to be more married men in those states? *Dr Lahey* Possibly. And of course they didn't have quite the enthusiasm as in other states.

Senator Hill In a state where you have a large rural population you have your small cities, your small centers, and pressure is strong. In a little town of 2,500 to 4,000 where everybody knows everybody else the pressure is much stronger than it would be in a great city like Boston or New York. *Dr Lahey* That is right. And I would like to tell you too—and I mean this sincerely and it isn't said critically—I just can't help but be impressed by the fact that the patriotism is higher in the smaller places. I don't know what there is about the city that dilutes it. But when you look at these figures that come out of the rural communities, you can't avoid that conclusion. When somebody says that the reason for that is that they can get better jobs in the Army, that doesn't hold water—

Senator Hill (interposing) In that connection have you made a breakdown in one of these states that is under its quota to see how the rural sections of that state compare with the urban sections? *Dr Lahey* We happen to have New York which is a pretty good state. We know that New York happens to have a chairman and a vice chairman. The chairman is in New York—I mean of Procurement and Assignment—and the vice chairman is in the northern part of the state. That part has done infinitely better than New York has that is New York City.

Commander Lapham We have here, however, a list of the percentages of the physicians, the effective physicians in every state who are on active duty now either in the Army or Navy, as compared with the percentage of rural population—

Dr Lahey (interposing) Ask him as to any state what percentage you want to know. Twenty-two per cent is the average number of doctors—

Commander Lapham (interposing) Of effective physicians.

Dr Lahey You must remember that there are 27,000 over 65 years of age, and we have arbitrarily set those—because they run to 102—at 33 per cent efficient, which means, in terms of manpower that you have got 9,000 efficient out of the 27,000. Now if you ask him as to any state he can give you the percentage as relates to urban and suburban.

Senator Hill We have been talking about the state of New York. You might follow through on that.

Commander Lapham As Dr Lahey says, the percentage of effective physicians throughout the country who are in service is about 22 per cent. In New York 26 per cent of the effective physicians are on active duty now, whereas the rural population is only 17.2 per cent, according to the Census of 1940. Alabama, which has 18 per cent of its effective physicians in the service, has a rural population of 69.8. So that actually New York has not done so badly in relation to its suburban.

Senator Pepper You mean that that percentage of its total rural population is in the Army? *Commander Lapham* That is the percentage of the total population which is rural. *Dr Lahey* We have been interested in trying to keep track as to what is happening to the rural population. Of course, Senator Pepper and Senator Hill, everybody that looks at this sensibly knows that the basic error in terms of being able to accomplish what we would all like is compulsion.

Senator Hill I was going to make an observation. It goes right back to the same proposition that we had in the days before we had our Selective Service, with reference to our armed forces, to the old volunteer system. You simply cannot get your maximum results from any kind of a volunteer system. You couldn't build your Army as you should build it, under a volunteer system. The British made a terrible mistake during the last war of starting out with a volunteer system when the flower of Britain's manhood was killed off in the early days of the war, and during the latter days of the war they didn't have this fine young manhood to be officers. We profited by their mistake and as soon as we went into the war following the leadership of the President, we passed this Selective Service Act.

I think we are going to reach the same conclusion—we are speaking now of a total war, such as we are in—we are going to have the Selective Service system extended to the entire population, and I think these figures show that.

Commander Lapham On the other hand, sir, from the standpoint of the physicians in this country, they have done remarkably well, there are 10,000 more physicians in the service now than there were at the end of the last war.

Senator Hill Oh, let me say this to you, I hope nothing that I have said to you will be construed in any way as a criticism, they have done wonderfully well. But you can't gage this thing today by men going into the armed services. In a total war you have got to be put on a basis, as I have said, of meeting your over-all needs, your total needs, your civilian needs as well as your military and naval needs. The only way in my opinion that you can meet those needs, on the most efficient basis, is by an over-all selective service.

All honor to the doctors for the way they have responded, I am sure there is no group in America that has responded any finer than they have.

Dr. Lahey What happens under this system is that the Army, the Navy and Aviation requisition what they want in the way of doctors. Whether they requisition more than they want, to be on the safe side, that is not our business! We don't know

Senator Pepper Now, Doctor, on this last point that you just suggested, you act upon the directions of the Army and Navy and Air Service in the procurement of physicians? *Dr. Lahey* Yes, they set a figure as to what they want.

Senator Pepper And it is your job to get it? *Dr. Lahey* Yes, and this I would like to get before you, that we not only have the figure that they requested as of January 1st, but we are around 127 ahead of them. So we are up to the figure that they requested as of the first of January.

Senator Pepper In other words, like the draft boards, you have met your quota? *Dr. Lahey* Yes, sir.

Senator Pepper Do they tell you what sections of the country they are to come from? *Dr. Lahey* No, sir.

Senator Pepper Did they give you the various classifications that they wanted, or did they tell you to get so many doctors? *Dr. Lahey* They set certain standards as to age groups.

Senator Pepper As you said a while ago, less than 45, or less than 37 for troop service? *Dr. Lahey* Yes.

Senator Pepper You are primarily, then, the medical procurement agency or the doctor procurement agency for the armed services? *Dr. Lahey* That is right, that is the purpose of this service.

Senator Pepper Did anybody in the government, so far as you know, at the time they gave you one of those requisitions, consider that requisition, either at that point or before it was issued, to determine whether or not in the first place the Army needed that many doctors in comparison with their needs and in comparison with what other countries similarly situated were using, and, if they needed that many, whether they needed them all at that time or not, or whether the civilian population could afford to give up that many doctors without, as Senator Hill pointed out, the total war effort in another direction being hampered? Was there any such overall decision ever made on such a requisition, to your knowledge? *Dr. Lahey* That question presents quite a large order, but I should say that in general the answer to it would be no.

Senator Pepper In other words the board of which you are the distinguished chairman did not consider that you had the authority to pass on the propriety or accuracy or excessiveness of these requisitions, your job was to fill the quota? *Dr. Lahey* I would put it this way. At no time—and this isn't critical—have we been consulted as to the authenticity of figures. We only get a requisition such as from Aviation, the first one was "We want 6,100 doctors by January 1st." Recently it was 2,400 more than they wanted. And from the Army without stating the figures—although I talked with both Surgeon Generals this morning so they would know I was

coming here—but not to state figures, they say, "We want this many doctors by the end of the year." Left to us was the problem of trying to protect the public.

Senator Pepper Do you know whether the head of the Public Health Service was ever consulted by the Army or the armed services to know whether the civilian population could give up that many doctors or not? *Commander Lapham* Not that I know of. *Dr. Lahey* But he and his representatives have been in on a good bit of the consideration of all of these problems.

Senator Pepper But you don't know of any board, of your personal knowledge, or any agency, which has sat down and viewed this overall problem of the needs for medical services by the armed forces and also by the civilian population? *Commander Lapham* Except our own board.

Senator Pepper And as you say, your own board did not have authority to do that? *Commander Lapham* That is right. *Dr. Lahey* Of course, as long as there is a surplus, it is easy—that we all know—it is only when we get toward the bottom of the barrel that you really get down to the need for consideration, and without being dramatic about it, from the standpoint of our responsibility to the public, we consider that we are getting close to the bottom of the barrel.

Senator Pepper And in some areas—*Dr. Lahey* (interposing) We are at the bottom. Because of that I have had in my mind—and I am sure the other members of the board have had in their minds—the need of a better coordinated effort and a better explanation as to why these men are wanted. So next Saturday morning we have requested that the Surgeon General of the Army, the Surgeon General of the Navy, of Aviation, of Public Health, General Hershey, a representative of the Secretary of War, and Mr. McNutt, be present at a meeting.

Senator Pepper But, Doctor, unless you are vested with some authority different from what you already possess, when you have this conference and you have made that very able speech of which you are capable, then these gentlemen can say, "Thank you very much Doctor, Boston is a lovely city, we hope we may drop in and see you sometime, we enjoyed hearing you"—and then walk right out and send you another directive. There isn't much you can do about it, I would assume, the way the thing is presently organized. It is a familiar story to us, of course, because we have been seeing the same thing happen in other areas where for example, men are being pulled out of key positions in industry, all over the country. We are not blaming the Army for wanting them because they have got a job to do.

Senator Hill But the same pattern follows right through.

Dr. Lahey I am always a little sensitive lest I be thought critical, because after all I came to Washington a little uncertain about what I would be able to accomplish after functioning more or less as a beneficent dictator in a clinic where I could hire, and fire, and not be accountable to any one. But I will say that really I have received excellent and complete cooperation and willingness and with respect to the Surgeon Generals' teams, when we said to them, "These states are overdrawn and we want the recruiting teams out," they went out and we have now recruiting teams only in the five states that are below their quotas.

Dr. Lamb How long has that been Doctor? *Dr. Lahey* I can't tell you. *Commander Lapham* That has happened from time to time.

Dr. Lamb When were those recruiting teams stopped except for these five states? *Commander Lapham* As a matter of fact they are being withdrawn from some states now but very shortly after we requested them to they usually have withdrawn their recruiting teams. *Dr. Lahey* And there is a directive, and order from General Ullo, that they shall be taken out.

Dr. Lamb What is the date of that? *Commander Lapham* That was within two weeks. *Dr. Lahey* I have talked with the Surgeon General from time to time concerning the necessity of withdrawing these teams.

Dr. Lamb As I see it, Doctor the operations of the Procurement and Assignment Board have been very much like those of the Selective Service. You have been more or less parallel with them for the medical profession? *Dr. Lahey* If we just had half of their authority.

Dr. Lamb With the exception that you don't have as much authority as they do? *Dr. Lahey* That is right.

Dr. Lamb But the final determinations are not up to you and the pressure as on the Selective Service to recruit the emphasis is entirely from the military forces for recruiting? *Dr. Lahey* That is right. I would think too without criticism, that there have been individuals representing the military forces who have felt only the responsibility of getting them in, and we know that in certain areas I have had to go to the Surgeon

General and say, "You must stop telling these doctors that they will either get into the service or you will put a gun on their shoulder."

Dr Lamb As far as that is concerned, some doctors have had guns put on their shoulders, have they not? *Dr Lahey* That is right.

Dr Lamb Would you say that there are many doctors now serving as privates in the Army? *Commander Lapham* There have been a few and it has been a good thing in some instances. For instance, in New York City eight or ten of them were inducted as privates. *Dr Lahey* It has been a stimulating thing to the men who have delayed beyond a reasonable point, who are really available.

Dr Lamb As far as the powers of compulsion are concerned, suppose that the armed forces had had the power of compulsion at the start of the war, and suppose that they had exercised it as they have exercised their recruiting power, would you not have had approximately the same number of doctors in the services today that you now have, or perhaps even more? *Dr Lahey* That is right.

Dr Lamb In other words, it was not compulsion alone that was lacking in this particular situation. The number of doctors, and their distribution in the armed forces or in civilian life was not affected as directly by the lack of compulsion as it was by the absence, on the part of the military services, of some plan for balancing civilian as against military needs. *Dr Lahey* If the Army had had the authority, plus a plan for equalized distribution, it would have worked all right. But if they had the authority without that plan, we would probably have been a good deal worse off than we are.

Dr Lamb Precisely. The number of doctors who have been taken in already, in proportion to the total doctor effectives, is already sizable, wouldn't you say? *Dr Lahey* Suppose I recite the figures although they may be confusing. If we say there are 176,000 doctors in this country—

Dr Lamb (interposing) That figure is arrived at how? *Dr Lahey* American Medical Association roster.

Dr Lamb How many of those are effective? *Dr Lahey* We start with 27,000 over 65. But you can begin to knock off some of those right away because—and these figures happen to be in my mind—you have 2,000 that are in the Navy and Army on full time, and they come off. You have 15,000 who are in positions which do not involve treating patients, they are on jobs in laboratories and so on, various jobs that do not involve the care of patients. So they aren't available for any kind of care. You have the 27,000 that I just spoke of, and if you count those as 33 per cent efficient, you knock off 18,000 more. You have 7,000 who are having a year's training or more, in medical schools, and you have 5,000 residents. A resident is a man who has gone beyond the stage of training but who stays on to become a specialist, or carries on in his process of being a specialist, some of the work in a hospital.

Dr Lamb That reduces it to just over 100,000? *Dr Lahey* No, I don't think so. *Commander Lapham* That is not correct, it is about 128,000 when you consider the effective physicians in the country.

Dr Lamb You are including some of the over 65 in that? *Commander Lapham* Yes, 18,000 over 65 come off instead of 27,000. There are 33 per cent available, so you can knock off 18,000. *Dr Lahey* So that brings you down—without again going into figures which the censors might not want published—that brings you down to around 120,000 or 130,000 doctors. Knock off what you want for the Army and you are down to around 80,000 doctors left for the civilian population. You start with 130,000,000 and when you figure that the Navy takes care not only of its own personnel but it also takes care of about 2,000,000 civilians their associated civilians, besides, and that the Army is taking care of some of their civilians, you can roughly knock off 10,000,000 from the 130,000,000, which leaves 80,000 doctors for 120,000,000 men, which is roughly 1 doctor to 1,500 people. But that is very uneven.

That brings us down to about 1 in 900 in New York State. To show you how the problem gets complicated, I have just come from Omaha where I met all the doctors in the Corps Area there in the Procurement and Assignment Service, and it gets down, as it does in South Carolina or even in certain parts of Alabama, to 1 to 3,000 or 4,000 and even more difficult than that, because they live in rural communities. The first time that it gets put up to us is that living in rural communities they can't even get to centers of medicine because they can't get gasoline and tires with which to get there.

Senator Hill You spoke of 1 doctor to 1,500 population, what would be the ideal in your opinion? *Dr Lahey* I think 1 to 1,500 is excellent. Before the war it was 1 to 975. *Commander Lapham* But that includes the whole 176,000, and

we know that a good many of them were not giving direct medical care. *Dr Lahey* I would say that 1 to 1,500 is not only good but it approaches luxury a little bit.

Dr Weber Do you feel that prior to the war we had a sufficient medical personnel for the health of the nation? *Dr Lahey* Yes.

Dr Lamb If it had been well distributed? *Dr Lahey* Yes.

Dr Lamb But it was not? *Dr Lahey* No. For instance, I know these figures—again before the war—I know that South Carolina was 1 to 4,100 of population.

Dr Lamb And they have taken what per cent from them? *Commander Lapham* Their quota is 170.

Dr Weber So that would leave them what? *Commander Lapham* Of course we base these quotas—*Dr Lahey* (interposing) These quotas were balanced and weighted. *Commander Lapham* One to 1,500 was the basis of the quota.

Senator Pepper But they were already behind in South Carolina before the war started? *Dr Lahey* That is right.

Dr Lamb So that perhaps the quota originally should have been so distributed that the city of New York would have been much higher than the one you put? *Dr Lahey* That is what I meant when I said that the quota was weighted in favor of where they had the greater number of doctors.

Dr Lamb What I meant was that if you had a ratio of 1 to 4,100 in South Carolina before the war, perhaps you should not have taken any from South Carolina, perhaps they should all have been taken from New York? *Dr Lahey* Well, we would like to have done so.

(Discussion off the record.)

Dr Lamb Now, Doctor, to go back to your figure of 80,000 which is the number presently available for the public, if the Army maintains its present ratio of 1 to whatever is the number of men, 130 or 140, whatever it may be—*Dr Lahey* (interposing) I can tell you that. In the Navy it is at 65 and in the Army it is at 72.

Dr Lamb Per thousand? *Dr Lahey* That is right. In the last war—so you can have a comparison—in France, in the A. E. F., you had 66 per thousand, and in training back here you had 10.4 per thousand.

Dr Lamb So that the thing figures out to about 135 men per doctor. Now if they maintain that ratio of 135 men per doctor, and if we have a 7,500,000 man army, that indicates that we are going to have to take another 30,000 doctors out of our present supply? *Dr Lahey* That is what the meeting Saturday morning is called for.

Dr Lamb And if we take that number out of our present supply we are going to be in trouble? *Dr Lahey* We have just told the armed forces that they just can't go on at the present rate and take them out at that rate. We believe that if you ask industry and the civilians to accept a lower grade that you must ask it as a coordinated reduction of demands on the part of the Army.

Senator Hill Speaking about that doctor, we know we have made tremendous strides in saving manpower in many of our production industries. For instance, it takes only one-half the manpower now to build a certain cargo airplane that it did when Pearl Harbor occurred. Have they worked out anything to save this medical manpower? *Dr Lahey* The only thing I can tell you is that there have been two things. I talked with the Surgeon General this morning, and the Medical Administrative Corps that is now operating at Camp Pickett and two other camps will, when the program is completed, replace 7,500 doctors with civilians who will be trained in medical administrative lines, they will replace physicians.

When that program is completed, how many men it will produce, I don't know. I have heard figures about how many per month they turn out, around 700. I believe was the figure. I don't know whether or not that is accurate, and I don't suggest that it isn't, I just don't know. There is that plus the fact as you already know that the accelerated medical program will turn out approximately 6,500 men per year as opposed to 5,000 in previous years before they had this accelerated plan. To show you how you have to keep on your toes about this thing and how when you throw a pebble into a pond, where the ripples go no one knows just think of the implications of this 18 and 19 year old draft. Without some agreement with Selective Service you have dried up the supply of new doctors. There are some that have to be earmarked for medical schools.

Senator Hill In that connection, Doctor, I wonder if you have had any talks with General White, who is G-1 of the General Staff. He is the highest authority on personnel in the Army—that is his position occupies that status—or with the American Council on Education? It is my understanding that General White, and the others representing the War Department, and perhaps certain representatives of the Navy, and the

American Council on Education, are today endeavoring to work out plans—*Dr Lahey* (interposing) I don't believe we will have much difficulty.

Senator Hill I was just wondering whether you had been called in. If you haven't you certainly ought to be while they are working out these plans to provide for the education and training of some of those men who are about to be drafted, so we won't grind the seed corn. *Dr Lahey* We have a pretty good agreement with General Hershey that we will be called in. *Commander Lapham* Dr Elliott is working closely with us.

Senator Hill He is, perhaps, representing your particular group? *Dr Lahey* Yes.

Senator Hill We continue to see stories in the press about some 2,500 refugees, refugee doctors, I believe, here in this country. Do you know anything about that reservoir? *Dr Lahey* The thing of course that we meet with—and I have to face it all the time—is the doctor who says to me, "How can you expect me to go into the service when you preserve a refugee doctor from going into the service so that he can stay home and get my practice?" All right! I go to the Surgeon General and say to him, "What are you going to do with the refugee doctor?" and the poor man just can't answer me. He would like to handle them. I say to some of the people, "All right, why don't you take the refugee doctor?" Well, first of all they say that he frequently can't meet the requirements, educational requirements. Temperamentally he doesn't get on with some of the situations in which he finds himself. The FBI feel that with relatives in Germany who are susceptible to pressure, he is a dangerous person. But out comes a directive which I read this morning on my desk—and which Commander Lapham knows about—a statement to the effect that about the only thing they know about him is that you can put him in these dislocation areas where you need to dislocate a doctor, and that is about the only place they know.

Senator Hill When you say "dislocate," Doctor, what do you mean? *Dr Lahey* Relocate him, put him in Mobile, Wichita, Kansas, or some of these other places. On the other hand, three went to Norfolk and got turned down by the hospital that was complaining about the situation down there.

Senator Hill I wouldn't reflect on these refugees in any way, but I suppose they have doctors in these Japanese camps, don't they? *Dr Lahey* It has been repeatedly suggested to us that they be put out there. *Commander Lapham* They are using Japanese doctors out there now. *Dr Lahey* The problem of dislocating the refugee doctor isn't as simple as it sounds to us on the surface.

Senator Hill I can understand how a local doctor would deeply resent the government bringing in this doctor who wasn't even a citizen of our country—some are and some are not. *Commander Lapham* But the ones that aren't are the ones we are having the greatest difficulty with. *Dr Lahey* There originally came out a directive to the effect that any refugee physician, particularly a friendly ally, could join the Army and in three months he would be given his citizenship. That was simple, but that hasn't been done.

Senator Pepper That hasn't been adopted? *Dr Lahey* No and if you tell them that, you can't back it up.

Senator Pepper (interposing) Couldn't the Army take them in, would they need legislation to take them in? *Commander Lapham* No, but they didn't feel they could afford to take a great number of them in because of their background.

Senator Pepper Aren't there places where you could put them, that is, where they would be subject to assignment so that the dependable and responsible doctors would assign them to the type of work that would be useful and yet they wouldn't have a chance to give anybody an over-shot of something and kill them? *Commander Lapham* A great many of them are being used in medical schools and hospitals.

Dr Weber You mean that a directive was issued and that the Army and the Navy have been unwilling to follow the directive? *Dr Lahey* I think the Navy has an absolute rule that a man has to have been a citizen for ten years.

Senator Pepper There is nothing, I suppose, immobile about that rule if they wanted to change it to meet national policy? *Dr Lahey* My views about immobility have been greatly changed.

Senator Pepper You have discovered that the greatest principle in the world is inertia, haven't you? *Dr Lahey* I have. Let's again come to a simple thing, like the problems that confront us. We have a doctor that goes to Texas—let's pick that state because it isn't the place—a woman doctor. She says "I have made quite a contribution to come here and why should I, who have passed the National Board, be told by Texas, which doesn't recognize the National Board (and remember the place I am talking about isn't Texas), that if I want to fill a place down here I must pay \$25 and take an examination, and I am damned if I will." I don't blame her.

I thought it would be an excellent thing because I come from Massachusetts and because we have a biddable governor, one who is reasonable. I mean, that I should go to the state board of registration of medicine and to the state medical society and to the governor and say that it would be an excellent thing for me when I speak before the National Meeting of the State Secretaries of State Medical Societies in Chicago on November 19, to say that I bring from my own state the action of the governor during the war that he has lifted this interstate requirement and that any one that the Procurement and Assignment Service selects for the duration of the emergency can practice there. Well the governor agrees, the board of registration of medicine agrees, and the state medical society agrees, but the attorney general says it cannot be done unless it can be demonstrated that there is a need for dislocation within the state.

Senator Pepper It looks to me as if a proclamation of the governor could handle that.

Senator Hill I imagine that the statutes do not give the governor the power except under that one condition.

Dr Lahey I spent last Saturday afternoon in the Department of Justice while they formulated this action so that it would be national. That is just going to take months, Senator Pepper, to get done, and it is again one of the things that is going to hamper you in the dislocation of people.

Senator Pepper In that case it might be a situation which would justify action by the Congress? *Dr Lahey* That would be a very, very valuable thing.

We felt that the demand for doctors that came from the Army and Navy and Aviation was the priority interest. We said, "All right, that is what we must meet first." That has been met. Then we said, "The next priority interest is to assess the real needs of depleted areas because we can't do anything about dislocation until we know what the needs are." So we are in the process of assessing needs. Once having assessed them comes again the step that will be even more urgent than anything that you or I have considered. You can get a man in the Army—there is his conscience, his uniform, his accomplishment. But when you come to ask a man to give up a good practice and go down to Corpus Christi, and go down to your hot spot, Senator Pepper, Valparaiso, Florida.

Senator Hill (interposing) What about Pigeon Creek? *Dr Lahey* What have you got to offer him to go in there, because after all he goes in on his own hook?

Senator Pepper Of course the satisfaction of living in Florida would atone for any hardship, while in other states it would be a hardship. (Laughter) Doctor, if the situation suggests the necessity for an overall authority, preferably a civilian authority to pass upon the whole question of the allocation of this particular kind of manpower,—has your experience suggested to you that any well balanced program will have to be maintained in equilibrium only by an agency that can see the overall picture at one and the same time? *Dr Lahey* Well, I don't really feel quite competent to express an opinion for other than medicine.

Senator Pepper I am speaking only about manpower as affected by medicine. *Dr Lahey* I would say that so far medicine has been easy, again due to the surplus, and that the injuries have been relatively slight, due to surplus, but if the war runs along any great period of time it could present, under the present plan, great difficulties and dangers.

Senator Pepper If you don't have this central agency or central tribunal? *Dr Lahey* I believe Commander Lapham has something to say on that.

Senator Pepper Commander, what I was about to say is that if you do not have an overall authority, call it what you will, to keep in mind the needs of the whole nation, at home abroad civilian, military and naval at the same time is there not a great probability that you will have maladjustment and surplus and deficiency that will not give a well balanced program to the nation? *Commander Lapham* I am perfectly sure of that. You are speaking of an agency that would represent the military forces as well as the civilians?

Senator Pepper Yes, a group that would speak for the whole country and when it became necessary to allocate medical personnel, to military and civilian needs—in other words, whether you would lift the number of patients as it were that the doctor in the Army would have from 135 to 200, and cut the civilian population down to a doctor for each 1,800 or something like that—all that is a balance of interest. But if you haven't got the same two eyes looking at the whole problem at the same time, it is not unlikely that there will be maladjustment. *Commander Lapham* I see very little reason why Army and Navy and Public Health Service and Procurement and Assignment couldn't get together on that.

Senator Pepper Provided you had some way set up whereby there would be some umpire to resolve the difficulties? *Commander Lapham* Yes. *Dr Lahey* Will you let me say one thing there? I think that the Surgeon General of the Army works at a great disadvantage. He works through the Service of Supplies. On the other hand—and I don't mean to boom the Navy just because I have a Navy man with me—but Admiral McIntyre, for instance, has complete authority. He is only responsible to the Secretary of the Navy. I can go to Admiral McIntyre and say, "I want this"—and get it. Poor General Magee can't do that because he doesn't have the power and authority. He is responsible to General Somervell.

Senator Pepper And General Somervell determines the number of doctors that the Army shall have? *Dr Lahey* The authority finally comes down from there.

Senator Hill The truth of the business is that General Magee is under Somervell, Somervell is under Marshall, Marshall is under Stimson and of course Stimson is under the President. *Dr Lahey* I said to Admiral McIntyre, "How come I can say to you that I want to get this and that, and I get it snap bang, and General Magee can't get it?" He said, "The poor man just doesn't have the authority that I have with which to get it."

Dr Lamb In this meeting that you are going to have at the end of the week, will some machinery be set up for reviewing the use now being made by the armed services of the doctors they have? *Dr Lahey* I don't know how we have any authority to do it, but that has always interested all of us, naturally.

Dr Lamb We have the impression that a review would reveal that many of those doctors could be better used and be much more efficiently worked than they are being at the present time. *Dr Lahey* After all I feel that without accurate knowledge of how they are being utilized and distributed, it certainly is not within my power to be critical.

Senator Pepper But isn't it rather lamentable that there is nobody so far, that you know, who has the duty at the present time to speak for the civilian population and protect them? In other words the Army and the Navy have complete authority to tell you how many they want and so far you have been filling your quotas by their directives? *Dr Lahey* That is right.

Senator Pepper Now so far as we know—*Dr Lahey* (interposing) I would like to say this. We have told them that we have stopped for the year, I mean, that we will declare no more available.

Senator Pepper Well, it is a question as to whether or not in view of what you said in the beginning about the status that you occupy, that you are here by a directive, it is a question as to who has the final authority, like the armed services and the War Production Board. *Dr Lahey* That is right.

Senator Pepper But naturally the Army and the Navy would be less than human if they didn't think primarily about what was their need and try to supply that need, and I would do the same thing if I were in their place. *Dr Lahey* That is the thing that prompted this meeting for next Saturday.

Senator Pepper The President in the White House is representing the whole country, and we sitting here in Congress are representing the whole country, and we cannot sit by and allow one national interest to be emphasized over another if there is any way in which we can help it. We are thinking in terms of the whole country and somebody has got to make it. Of course we don't expect to make it, we are only raising the question as to whether it is necessary for some authority to be set up that will see the whole picture at the same time.

Senator Hill I should think that the very reason you stated was the reason for the setting up of the War Manpower Commission, that we might have some overall authority on this whole matter of manpower. But the War Manpower Commission has no statutory status and has no power, really, of itself. It was decreed by Executive Order of the President, and I suppose the only power that it might have would be some power that the President had indirectly in some way that he had gotten from some other act, not with this manpower question primarily in mind.

Senator Pepper You are under the War Manpower Commission? *Dr Lahey* Yes. *Commander Lapham* We have the responsibility of protecting the civilian needs, but we haven't the power.

Senator Pepper Is the War Manpower Commission supposed to be concerned with the nonmilitary aspects of manpower, or not? Does Mr McNutt have any authority to say, "I am very sorry Mr Army (or Mr Navy) but I will not recognize your requisitions in excess of so much, I don't feel that I can approve your requisitions for more than so many?" *Dr Lahey* I don't know. *Commander Lapham* We have

requested Mr McNutt and Mr McNutt has requested of the Army and the Navy the withdrawal of these recruiting teams. Of course there is a representative of the Army and of the Navy on the War Manpower Commission, so we presume they were taking into consideration the military strength as well as the civilian strength.

Senator Pepper I wonder if it would be considered impertinent on Mr McNutt's part or on the part of his representatives if, at this conference on Saturday, he makes certain recommendations to the Army and the Navy about the use of their personnel, the number of it, and that there are going to have to be certain reallocations and that they may have to release a few people back to South Carolina, say, and may have to release a few people back to Nevada, "You have a good many doctors from that state that you are going to have to turn loose. I am sorry to have to interfere with your arrangements, but that is the order of the Manpower Commission."

I am very sure they would think Mr McNutt was very much out of order. But that is what we face as a national dilemma when all these things are set up on separate programs and there is no unity overall. Except in the person of the President of the United States I don't know of anybody in Washington that has the authority to handle this. *Dr Lahey* That is why, in discussing this meeting on Saturday I used a word that I think settles the whole thing I said, "There must be a cooperative agreement as to what they need, and an irrevocable one about what they will demand."

Senator Pepper And there has got to be some agency that can pass judgment. That is, if you go in and say "I conscientiously don't think that the civilian population can spare more than a certain number" and the Army and the Navy say "We cannot run our Army and Navy without detriment to ourselves unless we have a certain number"—it you get into a situation like that somebody has to resolve that? *Dr Lahey* Yes, but there are circumstances that we do have to consider and that is that we have to remember that the Army as yet has really no experience tables on this war, and as the Surgeon General very properly said this morning—and I appreciate his position—if we get into an offensive war no one knows what will be the number of wounded and what will be the casualties and what will be required to take care of them.

Senator Pepper That is all true but I mean that the same overall agency will have to take that argument into consideration in the allocation. *Dr Lahey* I should think he would like to be relieved of some of the responsibility.

Senator Pepper There would have to be an umpire to reconcile the differences? *Dr Lahey* Yes.

Senator Pepper Doctor, whom did you say you expected to be present at that conference on Saturday? *Dr Lahey* General Hershey, General McGehee, General Grant (he is the Surgeon General of the Air Force) Admiral McIntyre all of the members of the Board of Procurement and Assignment, and Mr McNutt. We have had them together before but we really have never gotten a coordinated effort.

Senator Hill Have you had them together since the Army reached its decision to have an army of 7,500,000 men? *Dr Lahey* No. And we have to take the Navy into account also. *Senator*

Senator Hill They propose an army of 7,500,000 men by January of 1944, and they propose to jump the Navy by another half million.

Senator Pepper Do you handle procurement for both the Army the Navy and Aviation? *Dr Lahey* Yes.

Senator Pepper Likewise, if the Army sends you in a requisition you don't compare that with the Navy's requisition, or if the Navy sends you one, you don't compare that with the Army's? *Dr Lahey* I compare them, I know what they are.

Senator Pepper But you don't pass judgment on them? *Dr Lahey* That is right.

(Off the record discussion.)

Dr Lahey There have been a definite number of states in which we have been able to meet that within the state, such problems as a doctor giving part time, an afternoon, to a community, for instance, such things as a man in industry being able to devote one half of his day.

Senator Pepper I know at Valparaiso one of the men from our Public Health Service the other day was telling me that the Public Health Service assigned a doctor down there. He treats the people and they pay the Public Health Service, really, and the Public Health Service pays him a salary. He doesn't take fees from his patients, but they pay for his services and he turns that into the Department of Public Health. I wonder if that man had to take the state examination? *Dr Lahey* The Public Health man doesn't, no. *Commander Lapham* But he would have if he had gone there to practice.

medicine *Dr Lahay* On the other hand, without complimenting your state your state made a very generous gesture in terms of its willingness to meet a certain situation *Commander Lapham* The state medical association and the licensing board all approved the plan to bring this man in through the Public Health Service *Dr Lahay* You can't live with this situation without reading all the things that go with it

(Off the record discussion)

Senator Hill I don't want to embarrass you, Doctor, by any flattery, but I think I might as well say that there has been no other man in America, unless it was Dr Will Mayo, who has ever founded and established such a clinic as you did. In fact I think your feat has been more remarkable than Dr Mayo's feat for the reason that you went right into Boston, right there at Harvard, the oldest medical school, the oldest clinic in this country, or one of the very oldest, and right there in that center by Harvard University, Harvard Medical School and Harvard Clinic, Dr Lahay has established without question the greatest medical clinic in the country

Senator Pepper Before you conclude that eulogy I want to say that he is just as eloquent and effective in aiding the war effort as a civilian as I saw him before this thing occurred, as he has been since

Dr Weber Is it possible to get for the committee the actual number of doctors now serving as privates in the United States Army? *Dr Lahay* I would think the better way for you to do that would be to apply to the Surgeon General's office *Commander Lapham* They are privates a very short time, they are almost immediately taken into the Medical Corps. I doubt if there have been more than 15 or 20 in the entire United States. I may be wrong about that, but we hear of all of them and very few have come to our attention

Dr Weber Is it true that pediatricians and obstetricians have been recruited just as any other practitioner? *Dr Lahay* Yes, and eye doctors also, because after all they have a basic and fundamental knowledge of medicine

(Off the record discussion)

Senator Pepper Well, Doctor, you have been most helpful to us and we certainly do thank you, and you also *Commander*, thank you very much

TUESDAY, NOVEMBER 3

Present *Senator Pepper* Also present *Dr Robert K Lamb* and *Dr F P Weber*, special assistants to the committee

STATEMENT OF DR THOMAS PARRAN

Surgeon General U S Public Health Service

Senator Pepper Dr Parran, we are very glad to have you here. I will ask you if you will begin by indicating briefly the war duties and responsibilities of the United States Public Health Service

Dr Parran The war has brought a large number of problems to the Public Health Service which might be divided as follows. We furnish the medical service to the United States Coast Guard, and with the very large increase in that organization it has been necessary to recruit additional doctors for service aboard ships as well as at their shore establishments. Moreover the War Shipping Administration has asked us to carry out the medical work for that organization, supplying medical care to all of their maritime training places

The Office of Civilian Defense, nearly two years ago, soon after it was organized, asked us to provide the medical service for that organization and we have given reserve commissions to a very considerable number of doctors both in the central office and in the various areas

More recently, we have undertaken to organize a team of doctors in each of about 200 hospitals who will be available in the event of enemy action, to establish and staff the emergency base hospitals which would be necessary, and also to provide medical care for evacuees

The war has brought with it very, very large tasks. With the growth of industry naturally industrial hygiene has become accentuated

We are cooperating with the states in the matter of venereal disease control. As you know, under the provisions of Title VI of the Social Security Act, the provisions of the Venereal Disease Control Act, grants of monies are being given to states in connection with their regular health programs. Those programs have been adapted very materially to meet the war needs and emphasis has been given to the increased problems which have arisen in the war industry and in the military areas. Congress has given us additional funds under the title of Emergency Health and Sanitation with which we are carrying out a very substantial number of activities in the control of communicable diseases and providing basic health services in and around the cantonments

With the beginning of the national emergency we undertook to make detailed studies of health conditions in each of these war areas as they developed. Those studies furnished the basis for the appropriations of the Congress for community facilities under the Lanham Act. We have just completed the seventh of such survey of health and medical needs in the extramilitary war and industrial areas, a total of 410 such areas into which some 5,700,000 people have moved. These surveys specify the needs for water supplies, for sewage disposal provisions, for hospital facilities, health centers and housing requirements

Senator Pepper Doctor, could you give us the summaries of the requirements that you found by that survey? *Dr Parran* I shall be glad to, Senator, very glad to insert it in the record

Senator Pepper If you can, I would like to have you read off at least typical ones, for example, housing *Dr Parran* Housing requirements?

Senator Pepper Yes, if you have got that in Army districts, or by some sort of geographical units *Dr Parran* It is by individual areas and service units. With your permission I will give you the total. The housing units authorized in this area are 293,422

Senator Pepper What area is that now? *Dr Parran* In 410 areas which represent the major war industry and extramilitary areas. We have not included in this the large metropolitan centers, thinking that by their largeness they are able to take care of the increases in population, but we have included such places as Norfolk, Virginia, and on down to smaller size communities *Senator Pepper* Will you give that figure again? *Dr Parran* Units authorized 293,422 and the additional units required 603,000

Senator Pepper To accommodate the migratory workers that are expected in those several areas? *Dr Parran* Those who have come or it is expected will come

Senator Pepper That is necessary, in your opinion, by your survey in order to afford adequate housing conditions to those people? *Dr Parran* Yes, sir

Senator Pepper That relates primarily to adequate housing conditions just for the war workers, does it? You did not go back and pick up the civilian population and analyze the situation existing in those communities and think about lifting the local population up to adequate housing standards? *Dr Parran* No, this is new housing which is needed to take care of the people who are expected to come in or who have already come in. In the matter of hospital facilities, for example, these communities have 176,165 beds now. Additional beds already recommended by the Public Health Service under the Lanham Act, 20,493, additional beds needed, 14,242. The standard or the yardstick used in connection with this estimate is $4\frac{1}{2}$ hospital beds per thousand of the population

Senator Pepper Do those hospital needs relate to the war workers or to the whole population of the area you analyzed?

Dr Parran This is to bring up the ratio of hospital beds to $4\frac{1}{2}$ beds per thousand of the total population. We found it very difficult to separate out the needs for hospitals for one group of the population and another

Senator Pepper What percentage of the population would you say the survey covers? *Dr Parran* There have moved into these areas, as I have said 5,700,000 people. The normal population of these areas was 54,000,000 people, so it is slightly over a 10 per cent increase in population

Senator Pepper That survey then relates to the provision of hospital facilities for some 60,000,000 people? *Dr Parran* Essentially

Senator Pepper Out of a total population of 130,000,000? *Dr Parran* Yes

Mr Weber General, out of the 20,000 that have been recommended by the U S Public Health Service what number have actually been provided? *Dr Parran* Twenty-thousand hospital beds, total hospitals 334 estimated cost \$64,500,000. Number of projects recommended by the Public Health Service—the dates are a little different. This was as of October 1, 290 hospitals approved by the President 218 number under construction, 51 number of projects completed 2

Mr Weber And how many beds actually have been added? Do you know the number? *Dr Parran* Only two hospitals had been completed as of the date of this tabulation, which is about a month old. I do not recall the number of beds in those two projects

Senator Pepper Doctor, you mean since when? *Dr Parran* That is under the Lanham Act

Senator Pepper When was the Lanham Act passed, do you recall? *Dr Parran* I forgot the date of the first act, but I think it was in April 1941

Mr Weber There have been several acts, Senator

Dr Parran Additional appropriations and authorizations

Senator Pepper Yes, I know They come through this committee What I was trying to get at was the period of time in which this has been accomplished I mean, does it mean that the whole war construction program has produced two hospitals completed so far? *Dr Parran* That is what the record shows

Senator Pepper And those two hospitals have how many beds? *Dr Parran* I do not have the figure as to the number of beds in them Fifty-one additional projects are under construction

Senator Pepper Fifty-one additional projects are under construction? *Dr Parran* Yes This program has moved ahead very slowly *Senator*

Senator Pepper Is that because the health conditions have deteriorated very slowly or the need was very small? *Dr Parran* The need was great, but initially the hospitals asked for beds the construction of the usual character involving frequently much critical material, and then as the situation got tighter regarding materials they were trimmed down, they were asked to revise the plans to provide only for temporary construction The War Production Board has reviewed the project As you know, the responsibility for administering the Act is under the Public Works Agency, and in addition the War Production Board has reviewed the applications as to the critical materials In some instances we have revised our original recommendations to provide fewer beds and the cheaper type of construction, using less critical materials

Mr Weber General do you anticipate that those fifty one projects now under construction will be completed in the immediate future? Have any of them been stopped by Mr Nelson's order to the Federal Works Agency? *Dr Parran* I am not sure I cannot answer your question Perhaps some member of my staff who is here will be able to give you that answer

Senator Pepper You can have them come up and sit with you Doctor if you like *Dr Parran* We do not have the information They were stopped in the sense that the War Production Board refused initially to approve the original request or requests which involved more permanent types of construction using structural steel and other critical materials

Mr Weber So the whole program has been delayed because of shortage of critical materials, and now that the estimates have been revised you do not know whether the projects now under way will be completed? *Dr Parran* The Public Health Service part is only to review and survey as to the nature and extent of the unit in reference to hospitals, public water supplies, sewage systems health centers and a few garbage projects

Senator Pepper Doctor, would you not consider that the War Production Board would consult the head of the Public Health Service or some other medical agency before they stopped the hospital program or have they become directors of health as well as critical materials? *Dr Parran* It has not worked out the way you indicate, Senator When a large number of projects had been recommended by us and approved by the President, and contracts had not yet been let, the War Production Board issued a general order regarding all kinds of construction It was not that they were singling out hospitals, but it had to do with all kinds of construction for which they were trying to save critical materials The situation seems to have gotten tighter and tighter, as you know

Senator Pepper The hospitals were caught in that blanket order? *Dr Parran* The war supplies were caught in that order

Senator Pepper Did the War Production Board sit down with you and ask what you thought were absolutely essential health requirements and how narrowly they could carve it down to the bone? *Dr Parran* No, but I assume they had our certifications which went to the Federal Works Agency and were contained in the individual documents

Senator Pepper Are they doctors in the Federal Works Agency? Are they medical men? *Dr Parran* We act as medical health advisors to the Federal Works Agency

Senator Pepper So the point is that the material people decided the medical question of how many hospitals there ought to be in the country? *Dr Parran* I would not quite say that I think they decided how much steel could be spared from ships, tanks and other war weapons

Senator Pepper And how many lives could be sacrificed by inadequate hospital facilities in gaining that much critical material? Is not that essentially the question of balance of interest, what are you going to pay in public health for the things you gain in battleships airplanes and tanks? It is a balance of interest It is strange that no medical authority has been taken into the council in the determination of that question

Mr Weber General could I ask if you have the figures there on housing units that have been completed? I think you mentioned over 200,000 had been authorized as against an additional need that you estimate is over 600,000 How many of those 200,000 that have been authorized have actually been completed? *Dr Parran* I do not have that figure, Senator I know, continuing my general testimony that the Service pointed out the needs for additional water supplies, sewage disposal, and in some instances health centers

Senator Pepper Can you give us the same summaries for that, Doctor? *Dr Parran* Yes Public water supplies costing \$36,900,000, serving 3,394,000 people Additional capacity in gallons per day, 1,800,000, costing \$36,900,000, a distribution system serving a population 3,900,000 costing approximately \$50,000,000

On sewage disposal, additional population to be served 3,900,000 at a cost of approximately \$60,000,000, and treatment facilities costing \$57,000,000 Our estimates, I should say, in reference to sewage treatment, have needed to be revised downward At the present time, we are not recommending the construction of sewage treatment plants unless a nearby water supply would be very seriously threatened, and that while a desirable health measure we felt it was one in which we could lower our standards for the duration in order to save on materials

Senator Pepper Does that complete the summaries of the survey? *Dr Parran* Yes We have made an estimate that these communities need to spend for general public health approximately \$1 per capita They are spending now approximately one half that amount That about completes the information

Mr Weber General, would it be fair to say that these estimates of needed community facilities are unrealistic today in the face of material shortages? That is, you are able to show on the basis of migration of over 5,000,000 persons to urban areas having 54,000,000 persons that a certain number of community facilities, sewage disposal plants, housing units, hospitals and so on should be erected, but in actual fact despite the appropriation of funds, those facilities have not been constructed in the main *Dr Parran* That is right

Mr Weber There is no assurance—in fact, it appears that they will definitely not be constructed because of the orders of the W P B and because of the shortage of raw materials Would that be a fair statement? *Dr Parran* Yes All of us are trying to get along with the least possible In some instances, a water supply would be seriously threatened if sewage treatment were not provided, and those projects are receiving the approval of the War Production Board In connection with water supplies, we revised downward our original estimates The figures which I have given you represent what we think are the essential needs now in the light of present conditions

Mr Weber It has been stated that in the field of housing we may face rationing fairly shortly in certain critical communities Would it be your opinion that since it is not likely that the new community facilities will be constructed, that some methods of distributing or obtaining adequate community services will have to be worked out in regard to hospitals, water supplies, and so on? Is there any study being made in types of rationing or into the methods of distribution of those facilities?

Dr Parran Yes As regards housing, last January, before the United States Conference of Mayors, I recommended compulsory habitability in these war areas as a means of rationing housing The hospitals are being rationed now in the sense that patients who have operations that can be postponed are not taken and the length of time that a patient stays in the hospital has been reduced sharply In many instances obstetrical cases are sent home by ambulance after two to five days following the delivery if the case is a normal one That type of rationing is being practiced

Mr Weber That type of rationing already exists here in the District does it not? *Dr Parran* Yes

Mr Weber Particularly in regard to obstetrical cases? *Dr Parran* Yes

Senator Pepper Now, when you were given the directive or the general admonition to make these surveys you were told, as I understand you only to investigate those areas in which there have been migrations of war workers and what the additional need of the several communities into which such migrations came were because of the war *Dr Parran* Yes

Senator Pepper Now, did you contemplate in your survey bringing the level of the general population in housing and health facilities up to the standard that you think it ought to reach or did you deal just with these migrations providing physical facilities to take care of the migrations? *Dr Parran* More than that, especially in communities where the ratio of

population was relatively small in comparison with the total. The financial arrangement as to what proportion a city would pay and what proportion is borne out of the Latham Act is handled entirely by the Federal Works Agency.

Senator Pepper: So, you were confined in your survey to about 54,000,000 people, to communities housing about 54,000,000 people out of the 130,000,000 people. In the first place, you were kept out of areas where there was no war work going on and you were supposed to bring up community facilities where migrations occurred only to a level that would take care of the new people that come in? **Dr. Parran:** Essentially that.

Senator Pepper: Now, I assume you were aware of the probable shortage of materials and the like when you made your recommendations, and that you probably made them on a conservative basis at that time, did you not? **Dr. Parran:** Well, the service, maybe more than a year ago, a year and a half ago, before we realized what this war was going to be like, did make recommendations in certain instances for sewage treatment plants which we would not make today. We have tried to adjust our recommendations to the deepening war situation, and of course the scarcity of materials.

Senator Pepper: You recommended the number of hospitals that you thought were the minimum required? **Dr. Parran:** Four and one half per thousand population, yes.

Senator Pepper: Which made a total of 290 that you recommended? **Dr. Parran:** Two hundred and ninety have already been recommended, yes.

Senator Pepper: You recommended 290 and the President approved 218, and only 2 have been finished so far? **Dr. Parran:** Yes.

Senator Pepper: And it is doubtful as to whether the rest of them will be completed at all? **Dr. Parran:** Fifty-one are under construction, and many of them are well towards completion. That is I think it is likely that the total 218 will be constructed. Most of them are cantonment types of buildings and are for the areas most urgently needing hospital beds.

Senator Pepper: If only the 2 that are now completed are to be added to the facilities which existed when the war started, would you say the number was adequate? **Dr. Parran:** By no means.

Senator Pepper: If only the 51 that are in process of construction are completed, will they be adequate or inadequate? **Dr. Parran:** In order to provide the minimum adequate number of beds in these areas we think that a total of 34,000 beds should be constructed. Of those 20,000 have now been authorized and another 14,000 are recommended.

Senator Pepper: That is the minimum, in your opinion, that should be required? **Dr. Parran:** Yes.

Senator Pepper: What would be the effect of that minimum that you have recommended not being met in construction? **Dr. Parran:** A continued rationing of the beds with what we have, the best use of the available hospitals.

Senator Pepper: What will be its actual effect in terms of taking care of the people? **Dr. Parran:** Much less good medical care. It is difficult to forecast in terms of death rates and sickness rates.

Senator Pepper: Isn't it probable that that will reflect itself in more deaths, a higher rate of sickness and more incapacity on the part of those war workers who turn out war material? **Dr. Parran:** One would assume that certainly would be the case. But just the exact measure of it, I would not be prepared to say. On the other hand, Senator, I think all of us realize someone has to balance the need of hospitals up against the need for another tank or another ship.

Senator Pepper: Who is doing that now? **Dr. Parran:** I assume that is the responsibility of the War Production Board.

Senator Pepper: Are they doctors? **Dr. Parran:** No.

Senator Pepper: Have they made an estimate as to where that balance of interest would be by consultation with any medical authorities that you know? Have they appraised the probable effect of denying these hospital facilities to the communities upon the people and upon the production program? **Dr. Parran:** I cannot answer that.

Senator Pepper: Go ahead, Doctor. **Dr. Parran:** We have attempted to increase the number of nurses available in the country under appropriations given by the Congress. In 1940 there were about 35,000 nurses entering training schools, and in 1941 about 45,000 and this fall about 55,000.

In addition, we have just recommended to the hospitals of the country that they shorten their period of training nurses and specifically that after the end of two years' training the student nurses be moved out of the nurses' dormitories therefore making room for additional one-third students who can come in and start their training. This has been supplemented by a very active program carried on by the Red Cross under which 50,000 nurses aides are being trained this year, and 100,000

trained next year. Moreover, the Red Cross has given instruction in home nursing and the care of the sick to some half million people this year, and they hope to increase that to a million next year. The Public Health Service has undertaken to help the states in a number of ways, not only by grants of money but by the recruitment and assignment of doctors, engineers, nurses and other technicians, especially laboratory technicians. At the moment some 705 such people have been assigned for general health work, 50 for industrial hygiene work and 574 for venereal disease control work.

Senator Pepper: Doctor, let me interrupt you. Take the nurses you are now describing, how many nurses are there in the country? **Dr. Parran:** It is awfully hard to count them. About 300,000.

Senator Pepper: Have you made the survey of the number that are needed in the country? **Dr. Parran:** Yes.

Senator Pepper: How many? **Dr. Parran:** The armed forces need approximately 30,000 nurses, additional nurses.

Senator Pepper: Is that as a result of the survey you made? **Dr. Parran:** No, sir, that was reported by them.

Senator Pepper: You mean they say they need 30,000?

Dr. Parran: Yes. The hospitals of the country report approximately about a 30 per cent shortage in their ward nurses. That is not a reduction under the number of last year or the year before, but the increased patient load has brought the need for additional nurse service. Essentially we think all nursing needs will be met.

Senator Pepper: As to the actual number that you need?

Dr. Parran: Yes. The needs will be met by the training in the nurse training schools of 65,000 to 70,000 new students next year, and 55,000 to 60,000 this year. That we think will supply the number of nurses needed, especially if their services are supplemented with nurses aides and less well trained people. At the moment hospitals are using one trained nurse to 18 less well trained persons. In Great Britain they are using one trained nurse to four nurses' aides, less well trained.

Senator Pepper: Then, we are not adding but about 75,000 to the number of nurses in the country this year? **Dr. Parran:** That is approximately the amount.

Senator Pepper: And the training program is still a minimum of two years? **Dr. Parran:** Yes, but during the second year especially those nurses render ward service in addition to their training.

Senator Pepper: Is that 75,000 that we need for this year to be in training? **Dr. Parran:** I think so. In the first place, that is all that can be admitted and housed and given some instruction, and, moreover, with the competition of war industries of our women power it is going to be difficult to get more nurses than that, I anticipate. I shall feel very fortunate if we are able to step up the numbers to the quotas that I have mentioned.

Senator Pepper: Are those ladies getting anything while they are in training? **Dr. Parran:** Frequently they pay tuition.

Senator Pepper: You mean the nurses pay tuition for their training? **Dr. Parran:** Yes.

Senator Pepper: Well, apprentices in the factories do not pay tuition, do they? **Dr. Parran:** I think not.

Senator Pepper: Is there any reason why the nurses that are needed in the national defense have to pay tuition for their training? **Dr. Parran:** We have made available tuition to any prospective student nurse who is certified to us by the hospital as needing tuition.

Senator Pepper: What about the upkeep of that nurse while she is taking the training? What is she going to live on?

Dr. Parran: The whole system in the nurse setup in the past has been very chaotic.

Senator Pepper: That is not what I am concerned about. What the system has been in the past. Let us forget what the past has been, Doctor, but let us consider what the United States of America now needs and then how well we have met those needs. If there are 75,000 nurses needed this year or 100,000 nurses, then would not it be the duty of the Public Health Service to get the nurses in and get them in training and provide for the means of their upkeep while they are in training and then place them so they can best serve the population? **Dr. Parran:** We are attempting to do that under an appropriation with which we are aiding some 265 hospitals in giving a basic nurse training course at a cost of about \$350 per nurse.

Senator Pepper: That does not include housing and subsistence for the nurse? **Dr. Parran:** Except where the nurses need it.

Mr. Weber: How many hospitals have actually filed, and for how many nurses requests that their tuition be paid? **Dr. Parran:** Of the \$350, which is the average cost to the federal government for training a nurse, I would estimate that

one third of it is for tuition and the additional amount is for the added cost to the hospital for the instruction to the nurse.

Mr Weber Doctor, do you know how many nurses actually in round figures have been assisted? That is, we have a Federal subsidy for the NYA trainees, but we have no Federal subsidy for nurses. *Dr Parran* Twelve thousand nurses up to date, divided as follows: 9,200 new students, advanced training to 1,800 nurses, refresher courses to 1,000 nurses.

Senator Pepper Have the hospitals been recruiting the nurses of the Public Health Service? *Dr Parran* The hospitals have been recruiting the nurses.

Senator Pepper Pursuant to directions by the Public Health Service? *Dr Parran* Pursuant to plans jointly worked out with the training schools and ourselves.

Senator Pepper Suppose the Public Health Service said we ought to have an additional 150,000 nurses, and suppose the Public Health Service itself made the assignment or sought to recruit that 150,000 nurses, and suppose that those nurses were given enough money to provide for their subsistence and their tuition while they were in training, and then suppose that they were placed by the Public Health Service in institutions and in such places as they could get their training, do you think that the number needed would be available from the women population of the country? *Dr Parran* A limiting factor, Senator, is the housing facilities in the nurses' dormitories.

Senator Pepper As you said awhile ago, nurse training had been recommended in the hospitals of the country. What about the home, private service? What about that method of training? *Dr Parran* That method is being used in some instances, and can be extended still further. I think the nurse situation will be reasonably well met, will be adequately met if the nurse training schools will put their student nurses on a salary after the end of twenty-four months and move them out of the dormitories thereby making available one third of the space now in the dormitories.

Senator Pepper You said that the hospitals will do that. Have you got any assurance that they will do that? *Dr Parran* They are being pressed very hard, too, and I am hopeful most of them will, but there is no compulsion as far as the federal government is concerned.

Senator Pepper Is it right to be hopeful in a national emergency in respect to the provision of adequate nurses to serve the population? Do you lack the funds, or do you lack legislative authority to do what is necessary to protect the public health of the country, Doctor? *Dr Parran* I should like to see whether or not the nurse training schools undertake this program on a voluntary basis before being willing to recommend that the federal government itself take over the training of nurses. It is not as simple as training other people, because the training school is integrated with the hospital, it is difficult to separate that from the other, as you know.

Senator Pepper The federal government has taken over the training of soldiers, and it has taken over the training of certain war workers, has it not? It has provided training facilities for apprentices of one sort or another. Is there any reason why the federal government is not equally concerned about the health of its citizenry? *Dr Parran* I think the federal government is doing as much in terms of the individual nurse student as it is in reference to any of these other sectors, Senator.

Senator Pepper You are satisfied then that the program upon which you are working now adequately serves the needs of the American people? Are you willing to state that, Doctor? *Dr Parran* Yes, if the program we have outlined to the hospitals is carried out I think there should be no shortage of nurses.

Senator Pepper Is that in relation to the needs of the people? *Dr Parran* Yes.

Senator Pepper So, if you were outlining an ideal program to protect and preserve the public health of the United States you would not add to the number of nurses that are now being trained under your present program? *Dr Parran* That are now being trained and the number that are now being trained under the accelerated plan that I have described.

Senator Pepper Well, we are nearer perfection than than many of us have thought. *Dr Parran* The nurse training centers have stepped up their enrollment, as I said, from 35,000 to 55,000. A great many inactive nurses have come back on duty, a great many married nurses who have not been practicing are doing nursing work. The needs are being met in these several ways.

Senator Pepper Have you examined the situation in a lot of Southern counties to see how many nurses are available to the population of whole counties in this country? *Dr Parran* We have a survey of the nurses of the country broken down by counties.

Senator Pepper Are not there many counties in the United States where there is not a single accredited nurse? *Dr Parran* Yes. I am not sure that there are many such counties.

Senator Pepper Doctor, do you know that in the state of Florida, in some counties over half of the child deliveries are by midwives and not nurses? Would not a nurse be better to perform even that function than an ordinary midwife, or is a county that has no nurse in it or one nurse in it adequately served by nurses in the United States? *Dr Parran* No, it is not, Senator, but you think in these days we have got to do, as you described, arrive at a balance of interest as between the total amount of manpower that we have for one or another job? We haven't felt that in these days it was possible to develop for the whole population the sort of ideal health program which some of us have envisioned. I do not believe there is equipment, and there are certainly not the doctors available to carry out such a program. However, I think many needs are being met by people on a voluntary basis in ways that we had not envisioned before the war, as the self help in nursing, for instance, one family help to nurse another.

Senator Pepper In what you said, did you indicate that you are assuming the functions of Mr. McNutt in the distribution of manpower among the various needs of the country? *Dr Parran* No. I figure I am only one small claimant for manpower, Senator.

Senator Pepper I did not ask you a minute ago whether you thought we could afford to give the people all the nurses they need, I asked you how many nurses the country needed to preserve the health of the country. You said we did not need any more. *Dr Parran* I said some 75,000 additional nurses.

Senator Pepper Then, you tell me there are a lot of counties where there are no nurses at all, or maybe 1. Of course, that is pitifully inadequate. Yet you submit with some sense of futility, some sense of frustration, that they could not be given the number they ought to have. I would like to know whether you are testifying about what you think the government can afford to do in the sense you are representing the government or whether you are testifying from your knowledge of the needs of the country? I am not asking you what the governmental policy ought to be, we are trying to determine that here in the legislative branch of the government. What we want to know is what are the needs of the country and whether those needs are ever met. We will have to be determined by some authority or agency that will divide the nurses between the sickroom and factory and school, because it is the people we are dealing with right now, that is, the over-all needs. We are vitally concerned as to whether the public health is being sacrificed to some other need. Now, we are relying very heavily on you to be purely a reporter of the facts about the people of our country and their health, and their health needs. Now, in what way, if any, does the work of the Public Health Service tie in with that of the Procurement and Assignment Service? *Dr Parran* The Public Health Service does not offer commissions to any doctor who has not been cleared by the Procurement and Assignment Service as being not essential.

Senator Pepper How is the Procurement and Assignment Service operated? *Dr Parran* You mean in reference to the Public Health Service?

Senator Pepper How have they gotten doctors? *Dr Parran* They have made a census of the doctors of the country. They have asked the states to report, and the localities to report upon who are essential and who are not essential.

Senator Pepper Now, who makes that survey? *Dr Parran* The Procurement and Assignment Service with its regional and state committees.

Senator Pepper That was not made by the American Medical Association? *Dr Parran* Initially, the American Medical Association made a survey, and more recently the Procurement and Assignment Service, itself, made another survey.

Senator Pepper Dr. Lahey, the present chief of the Procurement and Assignment Service was formerly President of the American Medical Association? *Dr Parran* Last year.

Senator Pepper I assume the other members of the board are members of the American Medical Association. Now, as matter of fact, has the Procurement and Assignment Service determined the need of the Army and Navy for doctors that they recruited? *Dr Parran* Not so far as I know.

Senator Pepper Have you passed on the directives that have been issued by the Army and Navy to the Procurement and Assignment Service? *Dr Parran* No.

Senator Pepper So far as you know, nobody has represented the public in the decisions made as to the number of doctors needed by the Army and Navy? *Dr Parran* Presumably the medical department of the Army.

Senator Pepper They are in the Army, are they not? They are representing the Army and Navy, you would assume, would you not, Doctor? *Dr Parran* Oh, yes

Senator Pepper So, the public, so far as you know, has not been taken into consideration in the making of their plans about the needs of the Army and Navy, in the directives that have been issued to the Procurement and Assignment Service. Now, would you have approved, had it been submitted to you for determination, the South Carolina situation, for example, which already had one doctor to 4,100 people, contributing 170 per cent of its quota as weighted and determined by this Procurement and Assignment Service to the armed services in relation to the doctors? *Dr Parran* No. I think the Procurement and Assignment Service should have intensified its recruiting efforts in the states where there was a larger surplus rather than in the states which you say had a low ratio of doctors to the population and that ratio has gone down even more.

Senator Pepper And in some instances they took more than 200 per cent of their quota. *Dr Parran* I understand that is the case, yes, sir.

Senator Pepper Does the Public Health Service now have adequate data concerning the health needs and available medical facilities for the civilian population? *Dr Parran* We have information concerning the war areas in general.

Senator Pepper Only the war areas? *Dr Parran* Chiefly in the war areas.

Senator Pepper And the proportion of the whole population, that is, the number of people in those areas is estimated to be about 54,000,000 of the 130,000,000 of the country? *Dr Parran* Yes.

Senator Pepper So, even during the war you have not been given a directive to develop a national public health program, you have only been given a directive to provide certain additional facilities for migratory labor engaged in war work in certain communities of the country? *Dr Parran* Yes.

Senator Pepper Do you think that allocation of medical personnel between military services and civilian work should have been handled through the Public Health Service rather than through the Procurement and Assignment Service? *Dr Parran* I think the present arrangement is the best. As a matter of fact, after seeing the system as it was set up in Great Britain eighteen months ago, I discussed that system with the Health and Medical Committee and others, and perhaps was responsible to some extent for a separate group representing the medical and dental professions being set up to deal with this problem.

Senator Pepper You mean that system that ignores civilian needs for medical services is the best of all, in your opinion? *Dr Parran* No, the Procurement and Assignment Service has the responsibility, under the executive order creating it, of considering the needs of the civilian population as well as the military, to seek to secure doctors for military service with the least damage to civilian health and medical care.

Senator Pepper So far then they haven't performed their duty if they have neglected to protect the civilian population in that recruiting? *Dr Parran* The Procurement and Assignment Service itself frequently has not been the recruiting agency. The Army sent into fields all over the country a large number of men who recruited doctors directly without reference to the Procurement and Assignment Service.

Senator Pepper They were looking after the needs, of course, of the armed services. *Dr Parran* Yes.

Senator Pepper So, the system to date, as a matter of fact, is that there has been the Procurement and Assignment Service carrying out the directives of the Army and Navy, and the Army and Navy have been doing their own recruiting but nobody has been sitting in on the decision as to the number of doctors needed in the armed services so as to protect the civilian population. That is a fact, isn't it? *Dr Parran* Certainly there has been a very active recruiting.

Senator Pepper But nobody has been sitting in on their councils in determining the number of doctors needed so far to protect the civilian population. *Dr Parran* The Procurement and Assignment Service itself has attempted to limit the number of doctors going from certain areas, but they have found it very difficult to do, Senator. As you know, it is a voluntary group. We do not have a national service act, and in the absence of it it is pretty strong medicine to say to a doctor, "You may not bear arms for the country because you are one doctor for 4,000 people in the community." That is no responsibility on which he will agree. We may need to come to that. On the medical front the time may have arrived, I do not know. I do know there is a serious depletion of medical manpower in certain areas. With your permission, I should like to give you some examples of areas where the number of doctors is all too few.

Senator Pepper I realize that I started to say, is it not a fact that actual pressure has been put on a lot of doctors to make them come into the service with the threat that they would be drafted if they did not come into the service? *Dr Parran* That is true.

Senator Pepper I had a letter yesterday, which I sent to Dr Lahey for investigation, in which I was informed that a very competent doctor and surgeon, a physician and surgeon, had been injured while operating a tank. They put him in a tank corps. That may or may not be a question of fact, but I understood yesterday the testimony to be that some doctors had been taken in as privates by the Selective Service System.

Mr Weber Doctor, may I ask you a question there? The committee has been told that some doctors who have resisted such pressure have been drafted, have remained in the position of privates in the Army over a long period of time. Do you know whether that is factually true or not? *Dr Parran* I would doubt it. I would doubt that any qualified doctor is now serving as an enlisted man. Certainly, no case has come to my attention.

Mr Weber Going back for a moment to the question of recruiting, you say that the Army and Navy have had independent recruiting teams in the field other than the recruiting efforts made by the Procurement and Assignment Service. *Dr Parran* The Army has had teams in the field. The Navy apparently has been able to get a sufficient number of doctors without doing that.

Mr Weber So if the Procurement and Assignment Service had said to an individual, "It is better for you to stay in your community," the Army recruiting team could come to him and say, "We want you?" *Dr Parran* I think that has been stopped.

Mr Weber Do you know whether it has been stopped? *Dr Parran* I think I am reliably informed that it has been stopped, and was stopped some time ago. However, there is nothing to prevent a doctor in South Carolina who wants to join the Army from joining. The social pressures for young men to get into the service have impelled many people to feel that the best way to serve their country was in a military way and that makes it very difficult for any group in the state to say, "No, you cannot go." There is no law to keep such a man practicing in North Carolina or South Carolina. He can go to New York City and set up in practice there.

Senator Pepper In view of the situation that exists in some of the counties in the South, how can you reconcile the coercive measures that have been resorted to by the Procurement and Assignment Division in cooperation with Selective Service to force doctors into the service to which you referred a minute ago? *Dr Parran* It seems to me that the Army and Navy needs must be met first. That is a basic thesis on which all of us have been proceeding.

Senator Pepper By which, you mean that they are not subject to examination by anybody who has any concern for the civilian population? *Dr Parran* No, I am not saying that their tables of organization should not be subject to review at the cabinet level.

Senator Pepper As a matter of fact, at the present time there is no final authority to apportion doctors between military and civilian needs? *Dr Parran* No, there is not.

Senator Pepper Now, at the present time, the Army is taking in doctors at the rate of about 72 per thousand, and the Navy at the rate of about 65. *Dr Parran* So far as I know, the Army has not made public its ratio of doctors to strength.

Senator Pepper Well, Dr Lahey testified yesterday to those figures here before this committee. *Dr Parran* Yes.

Senator Pepper Now, if that rate is continued and we recruit an Army of 7,500,000 men what will happen to the civilian population of the United States with respect to doctors? *Dr Parran* I think, Senator, we can spare from civil practice a total of, let us say, 55,000 doctors, if we ration, if we spread the remaining doctors evenly in proportion to the needs of the population.

Senator Pepper How many do we need for the population, Doctor? Do you mean we need 50,000 more? *Dr Parran* No, a total of 50,000.

Senator Pepper How many would that be? *Dr Parran* About 170,000 doctors altogether in the United States. About 150,000 of them are effective doctors; they are practicing, the others have given up practice or their teaching work. In private practice there are about 125,000, that are in private practice or in the schools in full time teaching positions or in laboratory positions, in public health positions, all doctors other than those who are practicing private medical care. Now, out of those totals we find that there are 61,000 doctors between the ages of 45 and 64 of whom some 55,000 are in private practice.

There are about 8,000 women physicians. In other words, there is a pool of about 75,000 doctors ineligible for military service that consists of women or men over 45 and doctors with physical disabilities.

Senator Pepper You mean there would be about 75,000 left after the Army has the 50,000 to which you referred? *Dr Parran* The 75,000 ineligible because they are women, because they are over age, and because they have physical disabilities.

Senator Pepper Would that number be adequate to serve the civilian population in your opinion? *Dr Parran* No but out of the total of 170,000 doctors in the country, I think we could spare around 55,000.

Senator Pepper That would leave 120,000 or 125,000 doctors altogether? *Dr Parran* Yes.

Senator Pepper That would include all the disabled and partially defective, of course? *Dr Parran* That is right, that would give us a ratio of 1 doctor to about 1,500 people.

Senator Pepper And in your opinion is that an adequate number? *Dr Parran* I think we can get along with that number if their services are available evenly.

Senator Pepper That would require a distribution of the doctors over the country which is not now the case? *Dr Parran* That is right.

Senator Pepper It would require rationing of medical care and hospital facilities, would it not? *Dr Parran* Yes.

Senator Pepper And it would put medical service on the basis of need and not on the basis of ability to buy, would it not? *Dr Parran* That might follow, but not necessarily.

Senator Pepper So if that number were taken away and we had only the number you mentioned left, in order to give the country any sort of adequacy of service, all those conditions would have to occur? *Dr Parran* Unless the conditions of even availability of medical service in relation to the needs of the population were met there undoubtedly would be many places where there would be inadequate medical care as there are today.

Mr Weber General, just on that point, we know from normal occurrences in peacetime we are not going to obtain an even distribution of those 75,000 doctors without central direction. Now the question is, just to give you an example, the question of giving some income security to doctors in rural areas. *Dr Parran* That is true.

Mr Weber It is a question of rationing hospital facilities, a question of seeing to it that the industrial worker gets the services, let us say, first of the doctors that are available. All these steps to obtain a distribution of health services and facilities are going to require central direction. Are you prepared to recommend a national health program involving all of these aspects? *Dr Parran* I am not prepared now to recommend the compulsory allocation of doctors in advance of a national service act. I think there are many things which happened up to now that can be done. Many of these problems which seem so complicated, as we view them in the total really break down into a multiplicity of relatively simple problems.

Senator Pepper Like providing a doctor for one of the counties in Florida that has no doctor is? *Dr Parran* No, like providing a doctor and a dentist for Valparaiso, Florida, at the request of the State Defense Council. We were able to secure a doctor and dentist. They appointed them in the Public Health Service and assigned them there. Similarly we have assigned two doctors to the State Health Department of Virginia, for service in an emergency clinic, in a hospital in Norfolk. It is not always just getting a doctor, it is getting a particular kind of doctor. Maybe an orthopedic surgeon is needed in Vallejo, California, or again a pediatrician is needed somewhere else.

Senator Pepper What about South Carolina where there was one doctor to 4,500 people in peacetime and now there are many fewer doctors than that? What about that situation? *Dr Parran* If the State Health Department of South Carolina says to me that we need one or more doctors to properly protect the health of the people in one or another area in the state, we are prepared to recruit such men, put them in our reserve and assign them to this work, just as we assign doctors on the staff of venereal disease clinics to operate immunization clinics, child nurse clinics, and so forth.

Mr Weber The initiative depends on the state, it does not depend on you or the federal government? *Dr Parran* On our own initiative we investigate the situation and give the state the information as to what the situation is. I am inclined to think that many of these needs can be met. They can be met in two or three ways. In one instance, the Army might furlough a doctor back home, and from one point of view that is very desirable. He knows the people, he knows the community, and he can be available in some urgent situation.

Senator Pepper Doctor, what is the Public Health Service doing or recommending with respect to adding to the country's supply of doctors? *Dr Parran* The medical schools have increased their enrollment and are operating full around the clock, as you know. If that process is continued after the war I think we shall very probably have an adequate number of doctors.

Senator Pepper You mean when? After the war? *Dr Parran* Yes, when the men come back from service.

Senator Pepper Well, now, what is the Public Health Service doing on its own to insure a larger number of doctors in the schools? Is tuition and subsistence being offered to any men that are capable of taking medical training by the Public Health Service? *Dr Parran* No.

Senator Pepper None whatever? *Dr Parran* None. The number of qualified applicants for medical schools, however, is about double the number admitted year by year.

Senator Pepper You mean by that both mentally and financially qualified? *Dr Parran* Mentally qualified.

Senator Pepper How about the question of the financial disqualification to serve the country as a doctor? *Dr Parran* Well, in medical schools, as in every institution of higher learning, there is a higher ratio of boys and girls from the upper income groups, of course.

Senator Pepper That is the condition as it exists now, but we face a national shortage of doctors, do we not? *Dr Parran* We have a shortage now for military and civilian needs.

Senator Pepper We have a shortage now for military and civilian needs, and therefore we have the greatest public need for additional doctors, do we not? *Dr Parran* Yes, sir.

Senator Pepper Now, are the medical schools going to be left to their own initiative to solve that public need, or is that going to be a public responsibility which we as public officials will face? *Dr Parran* I do not think that is an urgent matter at the moment, Senator.

Senator Pepper You mean getting additional doctors in training is not an urgent matter now? *Dr Parran* The medical schools are taking all that they can train. They have two applicants for every person admitted.

Senator Pepper They have no more facilities for training doctors in the country, facilities that are not being employed? *Dr Parran* No they have not. *Senator Pepper* You could not train any more doctors? *Dr Parran* Perhaps some schools could be organized, but the first results would flow from that after four and one half or five years or more.

Senator Pepper There is no way that you could reduce the training period so as to get them qualified to render some assistance to the population? *Dr Parran* I do not think it can be reduced.

Senator Pepper What is the period that a doctor must go through his training now altogether? How many years? *Dr Parran* Formerly four scholastic years. It has been contracted into three now.

Senator Pepper How many more? *Dr Parran* One year of internship.

Senator Pepper You do not mean he takes his academic and medical courses in four years? *Dr Parran* The medical course follows after either two years of college or four years of college.

Senator Pepper How many years of medical school? *Dr Parran* Normally four years.

Senator Pepper So, it is a minimum of how many years now? *Dr Parran* From high school? *Senator Pepper* Yes. *Dr Parran* Nine scholastic years.

Senator Pepper So, if we start now to train doctors the first one will not come out of the assembly line for nine years? *Dr Parran* Oh, no, there are many qualified college students who are ready to go into medical school and will be graduated after three calendar years.

Senator Pepper After three years? *Dr Parran* Yes. *Senator Pepper* You cut the period of nurses down from three to two years? *Dr Parran* Yes.

Senator Pepper There has been no reduction in the period of the doctor's training? *Dr Parran* Not as yet.

Senator Pepper You do not think in an emergency it will be possible to diminish that period of training any? *Dr Parran* I am not prepared to answer that question, Senator. It requires a very wise balance as between numbers and quality.

Senator Pepper I understood from Dr Lahey or someone recently that they were putting even a good many civilians into a good many places of administrative capacity, for example, where doctors are now employed.

Mr Weber Seven thousand. *Senator Pepper* Some 7,000 civilians. I mean a laymen's unit where medical men had been put into administrative places, so they could release doctors that were in those places. *Dr*

Parran That is what is now being done in the general office I am not informed as to the Army practice, but in the state health departments we are doing that, in our own service we are doing that, we are using the less trained personnel to relieve the nurse and doctor.

Mr Weber Doctor, as I understand it, you are going to be present at this conference on Saturday called by Dr Lahey? *Dr Parran* I had a letter from McNutt saying he was going to the conference between the Procurement and Assignment Service and the Surgeon General.

Mr Weber What do you understand to be the function of that conference? *Dr Parran* I do not know.

Mr Weber Can we assume from your testimony this morning that you approve of the general work of Procurement and Assignment Service? *Dr Parran* That covers a good deal of territory. I think Dr Lahey would be the first to say that it has not functioned with 100 per cent efficiency. I do get the impression that it is functioning better as time goes on. They are very slow in getting under way. Then, there was the urgent need of the Army for people, and the Army cut across lots of go out and recruit doctors without working through Procurement and Assignment because Procurement and Assignment was so slow.

Mr Weber Do you think the recruiting team method has been stopped? *Dr Parran* I think it has been stopped. I think it should be stopped. I would raise the question as to whether or not we should go so far as to prohibit a doctor because he happens to be in South Carolina from joining the Army.

Senator Pepper Doctor, do you think it may not be necessary to send back some of these, for example, South Carolina doctors—back to their state? *Dr Parran* I suggested that as one method. I suggested also the possibility that the Public Health Service can still recruit some doctors from the areas where there is relatively a surplus and assign them for work in these communities. We are already helping the situation by assigning a considerable number of nurses, but that program can be stepped up greatly providing bedside nursing service for the people in these boom areas.

Senator Pepper In other words, it is another case of taking the copper miners, training them as soldiers, making them soldiers and then sending them back as copper miners again? *Dr Parran* If a doctor were sent back, that would be a comparable situation.

Senator Pepper All due to the error of government policy in the beginning, not contemplating civilian needs as well as the military needs of the country. Doctor, have you got any statistics on whether or not there are any diseases that are increasing as an incident of the war? Tuberculosis, for example? *Dr Parran* There is tendency for tuberculosis to increase, especially tuberculosis among young women. It is a tendency that is just beginning, but in view of the experience of the last war in Great Britain, in Germany, as well as even in the neutral European countries, we can forecast very definitely a rise in the tuberculosis rate.

Senator Pepper What are our plans for meeting that threat to the national health? *Dr Parran* The plans are before this committee, I think, in a national bill, to provide community and tuberculosis hospitals. Perhaps that was passed by the Senate and then died in the House here a couple of years ago.

Senator Pepper In other words, we have the same plan that we had a couple of years ago? *Dr Parran* A plan of constructing additional hospitals. I think will be needed, just as soon as we can get some materials.

Senator Pepper Were those plans contemplated in the 290 hospitals you recommended, of which the President approved 218? *Dr Parran* No, tuberculosis hospitals by administrative definition have been excluded from the terms of the Lanham Act.

Senator Pepper I mention that because you recall in Orlando, Florida, we have the first and the states only tuberculosis institution, and any increase in the size of those facilities has been flatly denied until after the war. *Dr Parran* Yes.

Senator Pepper So, if the 290 hospitals that you recommended are not going to be built, in all probability it is not likely that any hospitals will be built to take care of the tubercular patients then, is there? *Dr Parran* Certainly. I have seen very little hope of it.

Senator Pepper So, substantially, we do not have any plan to take care of the increased threat to national health that is coming along with the war? *Dr Parran* We have the plans but we have no prospect of action.

Senator Pepper I mean any plan that offers a prospect of success? *Dr Parran* Yes, of accomplishment.

Senator Pepper Doctor have studies been made as to how the war work by war workers has been affected by public health, or the health of those war workers? *Dr Parran* We

have very close records on the question of absenteeism from work on account of sickness and with the war drive or zeal of workers to keep up production. There has been no increase in industrial sickness as yet.

Senator Pepper Was there already any appreciable loss from industrial sickness in the United States before the war started? *Dr Parran* Oh, yes, sickness causes much lost time. Recently it was calculated that sick and injured war production workers lose 6,000,000 work days every month.

Senator Pepper Is that important, in your opinion, to war production? *Dr Parran* Tremendously important.

Senator Pepper Would it aid war production if that amount of loss could be diminished? *Dr Parran* It undoubtedly would.

Senator Pepper So that the public health then has a very direct relationship to war production and the strength of the Nation, does it not? *Dr Parran* No doubt of it.

Senator Pepper Have you at your fingertips, Doctor, the number of selectees that were turned down because they could not pass the physical examination for the Army and Navy? *Dr Parran* Approximately 30 per cent of the total were rejected. Now some of them are being taken into service even though they have defects which initially disqualified them.

Senator Pepper What is the rehabilitation program that the government now has under way for those rejects among the selectees? *Dr Parran* The President, last October, by executive order, delegated the authority to the Selective Service System, to General Hershey, and later some money was made available.

Senator Pepper Do you know how much? *Dr Parran* I do not know the amount.

Senator Pepper Five million dollars—less or more? *Dr Parran* I am sorry I do not have the figures. I can furnish it for the record. All the money that has been made available I think has not yet been used.

Senator Pepper You mean they found out that these selectees did not have these defects? *Dr Parran* No. They run into all sorts of difficulties. They tried the system in two states, Maryland and Virginia, and only a baker's dozen boys were finally made available for the Army.

Senator Pepper Can you give us the figure of the total number of rejected selectees that have been rehabilitated and made available to the armed services? *Dr Parran* Relatively few, except those for venereal diseases.

Senator Pepper What would be your best estimate as to the number? *Dr Parran* For the conditions other than venereal diseases I should say relatively few. That does not count the boys who tried to volunteer and were turned down because of defective teeth and then got their teeth patched up on their own initiative.

Senator Pepper Neither does it count the ones who tried to volunteer, were turned down and who did not correct the defect? *Dr Parran* That is right.

Senator Pepper The number of selectees rejected for physical deficiencies was about 30 per cent of the total number? *Dr Parran* Yes.

Senator Pepper Doctor, as a medical man how many of those rejects could have been made available for the services for the armed services by an adequate rehabilitation program?

Dr Parran Somewhere between one fourth and one half, nearer 25 per cent, could be made fully fit.

Senator Pepper At least 25 per cent of the 30 per cent? *Dr Parran* That is right.

Senator Pepper Could have been by an adequate rehabilitation program, made fit? *Dr Parran* That is right.

Senator Pepper In a nation which is struggling for enough men to man its Army its factories and its fields, isn't it in the national interest that we put into effect an adequate rehabilitation program? *Dr Parran* In my opinion it is, sir, yes sir.

Senator Pepper But except for the directive that the President gave to General Hershey and some money made available which yielded a total of only a few hundred so far, that is all that has been accomplished on this rehabilitation program? *Dr Parran* Yes. If I might say, plus the very substantial number of men with venereal diseases who have been treated or cured, or the disease has been arrested and thereby the men made available for service.

Senator Pepper What has been done with reference to those selectees with venereal diseases and who have been rejected? *Dr Parran* They have been pulled up and encouraged, in some cases required to take treatment. If they lapse in treatment the Selective Service boards are notified and those boards call the men up before them. The Selective Service board actually has no authority to require one to take treatment but under the state quarantine laws, with the substantially additional funds we have been giving to the states, a very active program has

been carried out I have heard of some instances of boys with syphilis, who seemed to cherish a little positivity in their blood so they would not be called up by Selective Service, and even in other instances of the employer holding the same point of view, otherwise he would lose a valuable factory or farm hand

Senator Pepper Has the Army taken in any of these venereally affected people and given them corrective treatment? *Dr Parran* Yes, beginning last spring they began to take the uncomplicated cases of gonorrhea, especially those cases acquired somewhere between the local board examination and the Army induction center. More recently they have announced they will take certain types of uncomplicated syphilis as well as gonorrhea as soon as hospital provision has been made. Those hospital provisions are being made and are available and just about ready in many places.

Senator Pepper Is it proper to ask you if you have made any recommendations about the rehabilitation of these selectee rejects, as to how they could be rehabilitated? *Dr Parran* Yes.

Senator Pepper Would you feel free to tell us what your recommendation has been? *Dr Parran* Yes. Two years ago in September the state health officers recommended to me that a law should be enacted which would make any selectee rejected because of physical defects a beneficiary of the federal government entitled to medical care, just as a certain group of the population is now entitled to medical care, merchant seamen, for example, and members of the armed forces. Later on, we participated in recommendations to the Administration which resulted in the assignment of this task to the Selective Service System.

Senator Pepper As a matter of fact, the Public Health Service has not been given the opportunity or the duty to take care of the selectee rejects, and tried to fit them for military service? *Dr Parran* With the exception of the venereal diseases.

Senator Pepper Between what ages were those selectee rejects generally? *Dr Parran* Between 21 and 30, the bulk of them.

Senator Pepper So one of the reasons for this necessity of taking the 18 and 19 year old draftees is due to the shortage of other men in the 20's for example? *Dr Parran* Yes.

Senator Pepper A number of whom might have been supplied by these physical rejects had they been properly rehabilitated? *Dr Parran* There are some 300,000 men who will have been rejected on account of venereal diseases. That number is being approached now. That is the total.

Senator Pepper And then a certain additional number has been rejected on account of general deficiency? *Dr Parran* Oh, yes.

Senator Pepper A quarter of whom as you said a while ago, could have been rehabilitated by an adequate program? *Dr Parran* Yes.

Senator Pepper The Army had not consulted with you, Doctor, as to how you can rehabilitate these rejects, as to whether you have a program that will achieve that result?

Dr Parran No, I think it is fair to say the Army has consistently been uninterested in taking the men in and rehabilitating them in the Army. Many of us have thought that that would be a very appropriate way of handling the problem. The conditioning battalions of men, for example, would be under control, while in civil life there is no control over whether or not a selectee wishes to cherish his hernia or to get it fixed, let us say.

Senator Pepper I think all of that indicates then that the Army and the Navy, and the nation, have a very vital interest in a healthy citizenry, does it not? *Dr Parran* There is no doubt about it.

Senator Pepper So the expenditure of money for the protection of public health is not an extravagant waste but it has come to be now a military necessity, has it not? *Dr Parran* It really has.

Senator Pepper And when we ignore its importance we are ignoring a very vital element in our military strength? *Dr Parran* Yes.

Senator Pepper Doctor, have you any recommendations to make to us as to how medical authority and money made available to the United States Public Health Service or to any other agency that is appropriate can more adequately meet the problem of the nation's health and strengthen the nation's ability to wage war? *Dr Parran* Senator, the most urgent needs can be met I think by additional funds for which estimates have been prepared and are now in the Bureau of the Budget.

Senator Pepper Does that affect the whole population or just these war areas where there are only 54,000,000 people located? *Dr Parran* It is chiefly for the war areas.

Senator Pepper Do the selectees, Doctor, that come on call by the Army come only from that group of communities, or do they come from the whole country?

Dr Parran By no means. The trouble is now, with the depletion of medical manpower, it would be almost impossible to get the doctors and dentists needed to do the rehabilitation job. Dental defects represent the largest source, and there is just not the dental manpower left in the civil population.

Senator Pepper Is there anything being done to augment the number of dentists in training by the government? *Dr Parran* No, the government has not taken any position in that.

Senator Pepper So we have got the case then, if I am summing it up correctly, of a method of procuring doctors which totally ignores a civilian population and its needs, we have got a palpable case of a great many people who are not able to serve in the armed services because of physical defects, at least one quarter of which are remedial if they had adequate medical attention, with the present shortage of doctors and nurses, except in the instance you mentioned about some of the nurses getting tuition, the government, itself nor the armed services have launched any program that has for its objective the training of additional doctors or any appreciable number of nurses, and the hospital program that you have recommended for even the military areas that have only 54,000,000 of the population in them has so far been realized to the extent of 2 hospitals completed and 51 under construction, and it is admitted that there is an increase in tuberculosis in the country, as I understand, due to the war, and there is no effective program under way to meet that menace, and 6,000,000 man hours a month are being lost by war workers because of bad health conditions, a good bit of which would be preventable by adequate public health programs, and there is not any essential program at present under way that is a correct statement of your summary, I believe? *Dr Parran* You paint too gloomy a picture on that, Senator. After all, we cannot help but compare the present situation with the past, because we move the present of today is the past of tomorrow. Compared with the situation in the last war we are immeasurably better off in reference to public health activities and the health structure in the country. In the last war we took a few dollars from Red Cross to lure occasional nurses. Now, Congress has appropriated \$11,000,000 under Title VI for the Public Health Service, \$12,500,000 for the Venereal Disease Act. Our estimates for emergency health and sanitation work, including malaria, will run from \$20,000,000 to \$25,000,000. Congress is appropriating several million dollars for the training of nurses. We are adding hospitals in all of the war production areas and establishing blood banks. I agree much more remains to be done.

Senator Pepper So altogether we are approaching an expenditure of nearly \$50,000,000 on those general objectives? *Dr Parran* Yes, around \$50,000,000.

Senator Pepper That is a little over \$4,000,000 a month? *Dr Parran* Add to that the hospitals we hope to get. *Senator Pepper* For 130,000,000 people? *Dr Parran* So that some progress has been made, and the general health conditions in the country are not bad.

Senator Pepper You mean as compared to the past? *Dr Parran* As compared to the past. They are not good enough, I agree. There has been a great tendency on the part of many people the press, to forecast an influenza epidemic. I do not think we have evidence to show that we shall or shall not have an epidemic. Certainly, one cannot say that there are any imminent signs, and yet influenza may strike without warning like a storm.

Senator Pepper And if influenza struck without warning like a storm in a state like South Carolina which in peacetime only had one doctor to 4,100 people and now has many less, the consequences would be very serious to the people affected, would they not? *Dr Parran* Yes. We have no specific cure for influenza but nursing and medical care are important in minimizing the mortality.

STATEMENT OF DR PAUL DE KRUIF

Senator Pepper Are you Dr Paul de Kruij or Mr Paul de Kruij? *Dr de Kruij* That depends, Senator, on the definition of "doctor."

Senator Pepper Why do you say that? *Dr de Kruij* I received my Ph.D. degree in bacteriology at the University of Michigan in 1916, and I am called "Doctor" by my associates in public health and scientific work, but recently I have been demoted from my doctor's degree, and in circles high in the medical profession I am now called "Mister."

Senator Pepper Who was it that was responsible for your demotion, Doctor? *Dr de Kruij* THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Senator Pepper Who is the doctor that publishes that journal? *Dr de Kruif* The author is the American Medical Association itself

Senator Pepper Who is responsible for the publication? *Dr de Kruif* The editor is Dr Morris Fishbein

Senator Pepper Doctor, you said you were a bacteriologist by training? *Dr de Kruif* Yes sir

Senator Pepper Will you give us a little bit of your own background and experience? *Dr de Kruif* Briefly, I taught bacteriology and did bacteriological research in the University of Michigan from 1912 to 1920, with eighteen months out during my service during the war as a captain in the Sanitary Corps of the United States Army. From 1920 to 1922 I was bacteriologist at the Rockefeller Institute for Medical Research. I then left the Rockefeller Institute for Medical Research and began to devote my time to medical reporting for lay periodicals. In addition to that, I have kept in touch constantly with medical scientific work. I have participated in it at the Kettering Institute of Medical Research at Dayton, Ohio, as consultant in their work in research on the treatment of syphilis, and I am now serving as assistant to the president of the Board of Health of Chicago in charge of venereal disease control activities, and I am also serving as consultant to the Michigan State Health Department laboratories

Senator Pepper Doctor, you have been the author of certain publications? *Dr de Kruif* Yes, sir

Senator Pepper What are those? *Dr de Kruif* Certain books, among them "Microbe Hunters," "Men Against Death," "The Fight for Life," and I am also a roving editor and medical reporter for the *Reader's Digest*

Senator Pepper Doctor from your wide experience in observing public health in this country, what would you say about the adequacy of the medical facilities, hospitals, and doctors that are now available to the people of this country? *Dr de Kruif* I think they are inadequate

Senator Pepper What causes you to say that? *Dr de Kruif* I say that from my experience in investigating the situation in regard to medical care, in regard to public health activities, in regard to scientific research in respect to a certain group of disease conditions

Senator Pepper Well, now, what is the effect on the population of that inadequacy? A larger number of people die, a larger number of people are disabled by illness than would otherwise die and be disabled? *Dr de Kruif* Yes, sir. I think many, many thousands of lives could be saved, and the level of strength and health of millions of people could be lifted if we had adequate public health and medical care facilities

Senator Pepper Would you be willing to say that the 30 per cent of the number of selectees who were called and rejected because of physical defects might have been diminished had they had as children and citizens prior to their induction adequate medical care and attention? *Dr de Kruif* Yes, sir

Senator Pepper Would you say that the men who have been called into the armed services would have been better qualified physically as a whole had they had before they came into the service adequate medical care and attention? *Dr de Kruif* Yes, sir

Senator Pepper Would you say that the working efficiency of the nation's civilian population would be increased immeasurably by adequate medical care and attention? *Dr de Kruif* Yes, sir

Senator Pepper Well, now, Doctor, have you had any experience, or knowledge of, the method employed by the armed services now in the selection of their medical personnel? Do you know how it is done? *Dr de Kruif* I have heard Dr Parran testify as to how it is done, and I have also read the testimony before this committee as to how it is done

Senator Pepper Well, now, did you understand that preliminary to the actual functioning of the Procurement and Assignment Service that the American Medical Association made a survey of the doctors available in the country? *Dr de Kruif* I do not know if they did or not

Senator Pepper Well, suppose it were a fact that the American Medical Association made the original survey of the doctors who are available in the country, and then the recommendations as to those who are essential in the areas where they are located and those not essential, would you consider it appropriate that a private agency of that sort should make that kind of determination? *Dr de Kruif* I would not. *Senator Pepper* Why would you say that, Doctor? *Dr de Kruif* You understand Senator Pepper that I do not set myself up as an authority in this matter. I have not investigated it in a comprehensive way. As Will Rogers has said, all I know is what I read in the papers. On the other hand, I have had personal experience in a couple of situations in widely separated parts of the country

which would indicate that such a procedure is not an effective one in the determination of what doctor should go and what doctor should stay

Senator Pepper Would you be willing to give us the details of those cases? *Dr de Kruif* I would be glad to. The first one that comes to mind is the situation that arose in the state of Michigan and in the city of Detroit in the state of Michigan. Since 1936 I have been in close touch with the tuberculosis program. The city of Detroit is world famous for the progress it has made in the control of tuberculosis. The work there is built around a magnificent tuberculosis hospital known as the Herman Kieffer Hospital, and when the raid on the medical manpower of the country began the staff of physicians at the Herman Kieffer Hospital was cut from 16 to 2. It has to serve about 900 tuberculous persons, and several with other communicable diseases. It was only because of the existence in Detroit of some very determined men that the number of physicians was brought back to something near adequacy in the care of the sick in the Herman Kieffer Hospital

Senator Pepper So in spite of the generally admitted medical impression that tuberculosis is on the increase in such areas, that it is incident to war work, here was the one effective tuberculosis hospital which had its staff diminished from 16 to 2 by this agency? *Dr de Kruif* I would not say the one, I would say one of the most effective in the world

Senator Pepper One of the most effective in the world? *Dr de Kruif* Yes

Senator Pepper And it was only by the intervention of local people who understood the situation that that condition was stopped?

Dr de Kruif By very tough and courageous men, certainly. *Mr Weber* Would not it be fair to say, if the remaining 2 per cent were taken, it would have been closed? *Dr de Kruif* I could see no other answer, Mr Weber

Mr Weber They more or less reached what is called in Washington the bottom of the barrel. *Dr de Kruif* Their backs were to the wall

Senator Pepper Now, you said there was another case? *Dr de Kruif* Also in my state of Michigan, at the beginning of the raid on the medical manpower, the sanatoriums outside of Detroit, county sanatoriums, state sanatoriums were threatened with a serious depletion of their medical and technical personnel. Now, this was stopped through the intervention of a certain group of men who voluntarily went to the state committee on Procurement and Assignment and demanded and got the freezing of those men. That is in Michigan mind you. What has happened in regard to the personnel of other institutions in the rest of the country, I do not know. I know that those institutions were seriously threatened with a depletion of their personnel

Senator Pepper Now, how do you account for that, Doctor, in view of the medical knowledge that is supposed to have been possessed by these men who were making these recommendations and selections?

Dr de Kruif I can only account for it on the ground of their not being informed as to the importance of maintaining these institutions in full function in this emergency

Senator Pepper Are there other cases that have come to your attention? *Dr de Kruif* Yes. A rather flagrant one. It so happens that I am quite well acquainted with the work of one of the leaders in the field of nutrition. This man is Dr Tom Douglas Spies. He is the director of the Hillman Nutrition Clinic at the Hillman Hospital in Birmingham, Alabama. This nutrition clinic is not only nationally but world famous. It is the largest nutrition clinic in the United States. I think and its work since its founding in 1936 has been outstanding both in revealing the state of malnutrition existing in the southern part of our country and also in recommending means to cope with this widespread malnutrition. For example I am told that whereas some three out of ten men nationwide are rejected by the draft because of their physical disabilities in certain states, Southern states and Southeastern states in particular the figure is I believe, something like 7 out of 10. It is very high. A part of this disability is to be ascribed to malnutrition. This clinic, the Hillman Hospital Clinic, was unique in its service to the South in regard to the nutritional status of its population. Dr Spies was loath to join the armed forces. He is a bachelor, he is 38 years old, and consequently if you were not selecting men on the basis of their particular function but simply on the basis of their age, he would go into the Army, but he felt he was rendering the greatest possible service to his country by staying and directing the work of the Hillman Clinic. An effort was made by a person very high in authority in the American Medical Association to put the finger on Dr Spies and get him into the Army. This was only

prevented by the intervention of outside individuals who insisted to Dr Spies's local draft board that he should be declared essential.

Senator Pepper In other words, it was not a case of David sending Uriah to the front because he had a wife, because this man was a bachelor, but you mean to use your phrase that they did put the finger on him? *Dr de Kruif* They did put the finger on him. I think that fellow who was named Uriah, was not he the Hittite?

Senator Pepper Yes. *Dr de Kruif* David wanted him shot, so he sent him away to the front lines because he wanted his Jane. Your analogy is strongly apropos.

Senator Pepper You say there was an intervention in that case, with emphasis upon the importance of the work this man was doing and they were induced to desist from taking him into the armed services. *Dr de Kruif* Yes, sir. I think, Senator Pepper, that this case is so flagrant that it might well serve as a test case as a kind of a Dreyfus Case you know to show the people of the country what kind of funny business goes on in regard to the procurement or assignment that has gone on.

Senator Pepper So if that kind of thing occurs under the present system you would not think the present system of procurement and assignment of doctors was a desirable system? *Dr de Kruif* I would say more, sir—I think you are making an understatement, I think it is odiferous.

Senator Pepper Doctor, so far as you know has there been any regard in the action and functioning of the Procurement and Assignment Service for the needs of the civilian population? *Dr de Kruif* Not that I know of, sir.

Senator Pepper I think the statement was made that if the Army and Navy were to take the number of doctors they need there would still be enough doctors left to serve adequately the population. Do you concur in that statement? *Dr de Kruif* I do not think there ever were enough doctors to serve adequately the needs of the population. Maybe on Park Avenue, yes, but not in general in the country, not enough doctors nor good enough doctors. I am speaking of the ideal, and that is what we should set up as our base of reference.

Senator Pepper There were not enough doctors in peacetime, and you mean to say then that there could not be enough doctors even if less of them were taken away for the purpose of war? *Dr de Kruif* That seems to me to be a simple arithmetical conclusion.

Senator Pepper You said I believe there were maybe enough doctors on Park Avenue, because their medical services could be procured by people who had the money to buy it. *Dr de Kruif* By those who pay for it, yes, which I think is an infamous situation.

Senator Pepper In other words, a nation engaged in total war needs to use its manpower to the best advantage in every aspect of its national life, and that if the population is to be adequately served by its doctors, the population has got to have access to the doctors on the basis of need and not on the basis of the amount of money they have? *Dr de Kruif* I think even more than that. The men in the armed forces are the cream of the country in regard to their health and unless they are shot or wounded they need less medical attention by far than the rest of the people of the country and consequently it seems to me to be a strange situation that the medical care should be weighted so heavily in favor of the healthiest people of the country. Always assuming, of course that we are not going to have a battle in which a million will be wounded, or they maybe will say they will need these men in the event of a Stalingrad in this country.

Senator Pepper Doctor, how many members are there of the American Medical Association, do you know? *Dr de Kruif* I would not know.

Senator Pepper What percentage of all the qualified medical doctors in the country belong to the American Medical Association? *Dr de Kruif* I also cannot answer that. A very high percentage however.

Senator Pepper Is there any advantage to be gained by the doctor from being a member of the American Medical Association? *Dr de Kruif* Oh, yes.

Senator Pepper Do you happen to know from your knowledge of the profession and of the subject what additional training programs for doctors the American Medical Association has recommended for the emergency? *Dr de Kruif* I do not know, sir.

Senator Pepper The period of medical training, so far as you know, has not been diminished during the emergency, has it? *Dr de Kruif* No.

Senator Pepper In your opinion, would it be possible, in the public interest, to diminish the number of years presently required for the completion of a medical course? *Dr de Kruif*

I am not an M.D., and maybe I am not competent to state it, but I do think that there could be a speed up, yes.

Senator Pepper There has been a speed-up of 33½ per cent in the time of training required for nurses, I believe. *Dr de Kruif* Yes.

Senator Pepper From three years down to two years. *Dr de Kruif* Yes.

Senator Pepper And some one expressed the idea it might be compressed into one year of training. *Dr de Kruif* I believe so.

Senator Pepper Let me ask you this, Doctor. In your opinion is the country likely to get all the men that could be trained with the country's facilities so long as they have to be financially able, as they now must be, to sustain themselves or be maintained by the families over a period of seven years, say, and by the expenses of tuition and books and the other school expenses in addition to that, as well as it would if a man were to be able to take medical training merely by having the facilities available and the aptitude to take the training? *Dr de Kruif* No, no. I think the present method of selection, according to the economic level of the parents is an infamous one and also deprives us of a great deal of talent, potential talent that exists in the boys and girls of the lower economic levels.

Senator Pepper Roughly speaking, I wonder how much it would cost to complete the medical education of the ordinary man? *Dr de Kruif* You will have to get some figure on that from somebody else, Senator Pepper. I do not know how much that costs. It is a lot of money though. It is many thousands of dollars.

Senator Pepper Well, it would average \$1 000 a year probably. *Dr de Kruif* That is including the maintenance of the man?

Senator Pepper Yes. *Dr de Kruif* More than that, sir, I think.

Senator Pepper If it were only \$1 000 a year and it took seven years, that would be \$7 000. *Dr de Kruif* Yes.

Senator Pepper There is only one per cent of the population of the United States which makes an income of \$10 000 a year or over, I believe. *Dr de Kruif* Yes.

Senator Pepper So that a relatively small number of people have access to the medical schools of this country. *Dr de Kruif* Yes.

Senator Pepper Because a relatively small number of people are able to afford the training that the professional person requires. *Dr de Kruif* There are some efforts at present being made to meet the situation. I know of one. There may be other ones. One is being made by the W. K. Kellogg Foundation at Battle Creek, Michigan, at present.

Senator Pepper Is that a public foundation? *Dr de Kruif* No, a privately endowed foundation. There is being set aside a considerable sum of money for scholarships or fellowships for boys that need the medical education. Whether however, that will meet the needs of the situation I doubt. I am not sure, but I do not think so.

Senator Pepper You do not know of any plan the American Medical Association is formulating to make medical training accessible to a larger number of boys and girls? *Dr de Kruif* Not that I know of. So that I would not be accused of prejudice I must say that such may exist. I do not know of it.

Senator Pepper Well do you not regard one doctor to 1 500 people on an average as being enough doctors for the people do you? *Dr de Kruif* Not that they are being well taken care of, no, — as well as they could be.

Senator Pepper You are sure you would not regard one doctor for 4 100 people in South Carolina as enough? *Dr de Kruif* I think that is a horrible situation.

Senator Pepper And if the South Carolina doctors have been further depleted in number by giving 170 per cent of their quota as weighted by the American Medical Association, their plight is a very great one, isn't it? *Dr de Kruif* I would feel so, sir.

Senator Pepper Well Doctor, to get back to the Procurement and Assignment Service you do not regard then that agency, as presently constituted, as qualified either by disposition or general knowledge to speak for the civilian needs of the country, or to pass on the question of the allocation of medical manpower between the armed services and the civilian population? *Dr de Kruif* I do not think they are qualified, sir.

Senator Pepper Have you any suggestion as to how the matter ought to be handled? *Dr de Kruif* Yes.

Senator Pepper We would be very glad to have it. *Dr de Kruif* I think that first there should be appointed a fact finding commission with power to investigate the result of the present depletion in those areas which have been depleted. This com

mission should be composed of a mixed commission, maybe of a layman and two doctors who would be above suspicion of belonging to the group which consistently apologizes for the present adequacy of medical care

Mr Weber What are you referring to? The American Medical Association? *Dr de Kruif* Yes, sir That does not mean that these physicians should not belong to the American Medical Association

Mr Weber But you would be unwilling to see the top officials of that organization to be appointed on that fact-finding body? *Dr de Kruif* I do not think you would get much else but a whitewash if that happened

Mr Weber You said that they had offered no national health program to date in the war *Dr de Kruif* Not so far as I know Not a general national health program implemented by the federal government

Mr Weber Well, health is a war question, do you feel? *Dr de Kruif* Your question is an understatement What good are tanks, airplanes and battleships if you do not have the top men to man them?

Mr Weber If it is a war question, that means it is a national question, doesn't it? *Dr de Kruif* I do not think Michigan is fighting the Nazis and Japs alone

Mr Weber It is a primary concern of the national government? *Dr de Kruif* Certainly

Mr Weber Yet we have no national war health program at the present time? *Dr de Kruif* Not that I know of

Mr Weber We have nothing but scattered individual effort by states, localities, communities, and a separate group of doctors *Dr de Kruif* Yes

Mr Weber Without the leading professional organization of doctors for the defense of Americans at all *Dr de Kruif* So far as I know, that is true May I give you a case in point of what might be done right now, one specific instance, instead of indulging in these generalities?

Mr Weber Yes *Dr de Kruif* For example, at the present time many tuberculous men have been found by the screening of the selectees They gave x-ray examinations, a chest film, and they find a large number of tuberculous boys These are rejected, of course Now, the finding of those boys gives us an unprecedentedly powerful weapon to trace tuberculosis to its source These boys, every one is found, his name is known, his place of residence is known, and his family is known He has gotten his tuberculosis from somebody in his region, and when he is going back he is going to give tuberculosis to other people So that now, if there were in a national health program a T B controller, let us say, a federal man, with the facilities now at hand, he could institute what is known as an epidemiological campaign, and an active treatment campaign that would enormously accelerate the decline of tuberculosis and aid in its being wiped out

Mr Weber Where we find a man with a venereal disease and he is rejected they attempt to follow him up, or they do follow him up? *Dr de Kruif* Yes, there are some very good efforts in that direction

Mr Weber And in the case of T B also? *Dr de Kruif* No The venereal program is very much stronger than the tuberculosis program

Mr Weber Is tuberculosis increasing? *Dr de Kruif* In certain states

Mr Weber Would you mind naming them? Do you know any of them specifically? *Dr de Kruif* No, I will not name them now, but if you will communicate with the National Tuberculosis Association in New York, you can get a record of the cities where it is increasing, where the figures are higher in 1941—and 1940—than they have been in the past Baltimore has been one such city, I call to mind just now There are other ones

Mr Weber How about the state of Michigan? *Dr de Kruif* The situation in Michigan at the present time is as follows Detroit, because of its institution of a powerful tuberculosis program, in spite of the fact that it is the industrial high spot of the country so far as the strain upon the workers increasing tuberculosis, is actually continuing its downward trend in tuberculosis The state as a whole is maintaining its mortality on a level The city of Detroit is still going down thanks to the program that was begun in 1929, intensified in 1936 and still in full progress, thanks to a few determined men

For example, you asked how I would suggest that this thing be corrected As a specific instance, if you would call before your committee Dr Bruce H Douglas, the Health Commissioner of Detroit, and Dr E J O'Brien, member of the Michigan Sanatorium Commission, which has been the sparkplug the

leader, in the Detroit tuberculosis campaign, they would make recommendations to you that would thrill you, Senator Pepper, as to what could be done now

Senator Pepper Doctor, have your experiences led you to believe that we have been making an economical use of the nation's manpower? *Dr de Kruif* You mean in general?

Senator Pepper Yes *Dr de Kruif* I am not competent to judge on that, sir I could not pass on that

Senator Pepper What I mean is this We are now talking about a shortage of manpower The fields cannot be harvested, the various factories are having their output severely diminished because they haven't the employees We had to resort to the drafting of 18 and 19 year old boys in order to get enough men In spite of those stringencies for manpower we have been neglecting public health, which has a direct relationship to the effective manpower of the country Is not that a fair conclusion? *Dr de Kruif* Definitely so, sir

Senator Pepper So that a nation that did not try to rehabilitate the selectees whom it had rejected would not seem to be very much concerned about the economic use of its manpower, would it? *Dr de Kruif* I think that conclusion follows

Senator Pepper Would not you think that before a nation resorted to the draft of mothers to leave their homes and children and to work in factories that it would first try to see how many people there were, men and otherwise, that were capable of working except for physical defects and that could have the physical defects remedied so they would be effective workers? *Dr de Kruif* That would seem to me to be the first move to be made

Senator Pepper Would not it be natural to assume, before compulsion was resorted to to get people into the armed services and factories and fields, that we see how many people could be made to fit to volunteer for those various services? *Dr de Kruif* Yes, sir

Senator Pepper Then, isn't it essential, in dealing with the war manpower problem, that we deal with the nation's health, in your opinion? *Dr de Kruif* It would be fundamental to deal with the Nation's health, to do that

Senator Pepper So that any manpower program that leaves out of consideration the fullest use of the nation's facilities for protecting the public health is not a properly balanced or sufficiently comprehensive program? *Dr de Kruif* I feel that to be true

Senator Pepper This thing about the Nation's health is not just a frill or furbelow, as I understand you then, but an essential and vital matter in relation to the Nation's strength? *Dr de Kruif* I always put first not only essential and vital matter but the essential and vital matter in relation to the Nation's strength May I add one thing, sir?

Senator Pepper Yes *Dr de Kruif* Your point of view will be rebutted by those who say that the health of China, India, Poland, and Russia is so much worse than ours, that ours is wonderful Will you please remember that, Senator Pepper?

Senator Pepper I assume that you intimate that what we should think of is what our conditions are in respect to what they might be with adequate medical care *Dr de Kruif* Always I feel, sir, since we are arrogating to ourselves leadership in the world and among the allied nations, that the first thing we should do would be to put our house in order in regard to health

Senator Pepper Have you any figures or any information that would entitle you to make a comparison between what we have done in the way of providing public health facilities to our people and what the Germans have done in that respect? *Dr de Kruif* No, I cannot, sir Since the closing of the frontier, you know, since the war, I think very little is known about that Previous to the war, I think we got figures, but it was generally said among friends of mine that the Nazis took a great deal of care of the health of their soldiers and of their industrial workers too, but I am not an authority on that and I have no figures

Senator Pepper Did you have an opportunity to make any study of the Russian system before the war? *Dr de Kruif* No

Senator Pepper To know whether or not it was possible for the citizenry of Russia to get access to hospitals and to medical attention? *Dr de Kruif* I have read books about it, and one book in particular by Dr John Kingsbury and Sir Arthur Newsholme that related that such facilities are placed at the disposal of all the citizens However, how good those facilities and how accurate the Russian medical manpower and nursing manpower and scientific manpower are I do not know

Senator Pepper It is not maybe an outlandish assumption to make that a good deal of the fertility and strength that have been exhibited in the resistance of the Russians to the Germans

is attributed to among other things, those facilities and those conditions *Dr de Kruif* I do not know The Russians are hereditarily a healthy lot The Russian women do not seem to have much trouble in bearing children, because of the rapidity of parturition They bear their children very quickly The childbirth takes less time than it does in many other western countries and consequently you cannot say that it was the medical care that did it, because they are such tough, good people, you see

Senator Pepper It is not maybe too much to assume that it might be contributed to the medical care and attention that they have received that has made them a stronger people than they otherwise would be? *Dr de Kruif* I would not go on the witness stand and say to you, sir, that that was the case

Senator Pepper I can summarize one of the suggestions you made can I not, by saying that you believe that experience has proven that the American Medical Association whatever their virtues cannot be depended upon by the United States to provide an adequate complete and comprehensive public health program *Dr de Kruif* Not alone They should participate in it, but they cannot be depended upon to lead it and to organize it

Senator Pepper Such leadership and such responsibility must come primarily from the government and the people of the United States? *Dr de Kruif* Definitely

Senator Pepper Doctor, thank you very much *Dr de Kruif* Thank you Senator Pepper

Senator Pepper We are considering you an esteemed doctor *Dr de Kruif* May I say one thing, Senator?

Senator Pepper Yes *Dr de Kruif* You can always be sure it is all right to call a man a doctor who is a medicine doctor a dentist doctor, a horse doctor, a chiropractor, but not a man with a Ph D in bacteriology

FRIDAY NOVEMBER 6

Senator Pepper We appreciate very much your being here from your busy and constructive life and will welcome any statement Mr Kaiser, that you feel disposed to make affecting this question of manpower, the question of the public health, or any of the factors that enter into the efficient use of the nation's manpower

STATEMENT OF HENRY J KAISER SHIPBUILDER

ACCOMPANIED BY M MILLER AND DR SIDNEY GARFIELD
OF THE KAISER INDUSTRIES

Mr Kaiser On the question of manpower I would like it understood that I am not here to criticize any work that anyone is doing on the manpower situation who are working unquestionably very seriously and devotedly in the interests of the government, and anything that I present here is merely presented as suggestions with the hope that they will be helpful in getting directly the viewpoint of our experience in the areas in which we are working industrially There may be also weaknesses in our suggestions and they are presented with that view in mind with the idea of only being helpful In response to your request to appear, I have had, since that time all of the heads of our various organizations in the area study the problem, and asked them to come through jointly with a report, as well as asked a representative to come from there to be here with me in order that if there were any details that I was not familiar with, I could ask him and he report to you Likewise, the same thing on the medical situation Now I am presenting here first their problems These may seem critical, they are not critical, they are merely the problems And second is a suggestion which might solve those problems So I am not coming here only with the problems but I am coming here with a suggestion that might solve them

[After some preliminary remarks, *Mr Kaiser* said]

Mr Kaiser There is an apparent lack of coordination between Selective Service and War Manpower Commission There is no definite policy as to the priority of war industry or essential civilian industry with relation to Selective Service The employer, therefore, is not clear as to what program of training he should adopt because he doesn't know which personnel may be called or may voluntarily enlist and, therefore, cannot intelligently program his training schedule The present policy of Selective Service, by quotas, in each state in the Union is in our opinion, resulting in inefficient use of manpower by armed forces, war industry, and essential civilian industry Armed services are draining certain critical war industry and essential civilian production areas while other

areas have surplus This also is particularly true with respect to the medical situation While plans are under consideration, no definite action has been taken with respect to communities that are increasing in population and, therefore, should have a stabilized medical manpower

Senator Pepper Mr Kaiser, just as a preliminary background, you are employing at the present time substantially how many men? *Mr Kaiser* A quarter of a million

Senator Pepper Scattered over how large an area? *Mr Kaiser* It is a tremendous area

Senator Pepper How long have you been in the construction business, Mr Kaiser? *Mr Kaiser* Thirty years

[After submission of his proposals for control of manpower, *Mr Kaiser* said]

Mr Kaiser Right here on that question of taking care of these men, I would like to have Dr Garfield make a few statements so it will come in at this time, and I think it will show that we have the same problem there

Senator Pepper State your full name and address please, Doctor *Dr Garfield* Dr Sidney Garfield, Oakland, California

Senator Pepper Doctor, give us a little of your background, so that the record will contain it *Dr Garfield* I am in charge of the medical program of the Kaiser Shipyards, that is both South in Richmond, California, and up in Vancouver, Washington It has been Mr Kaiser's policy—

Senator Pepper (interposing) Just a minute are you a graduate of an approved medical school? *Dr Garfield* Yes, sir

Senator Pepper What is your school? *Dr Garfield* The University of Iowa

Senator Pepper All right, go right ahead

Mr Kaiser I would like to say this, that Dr Garfield started serving our medical end at, I think Parker Dam, and from there he went on through with us and gave us a great deal of service off and on until finally at Grand Coulee Dam we established probably one of the finest hospitals at Grand Coulee Dam in the State of Washington, with 3 operating rooms and 120 beds

Senator Pepper I had the thrill of visiting that project one time Mr Kaiser, while it was in the process of construction, by your kindness, and it was certainly an inspiration to me

Mr Kaiser I am glad it was, thank you At Grand Coulee we there found out what we really could accomplish in the way of giving attention to the medical care of the men, not only to their accidents but also to their health and we therefore proceeded in this industry to do the things that he will tell you about

Senator Pepper How many years now, altogether, have you been with the Kaiser Company, Dr Garfield? *Dr Garfield* Nine years

Senator Pepper Engaged primarily in protecting the health of the employees of these companies? *Dr Garfield* Yes, sir

Senator Pepper For the purpose of making them able to render more efficient work, primarily, to these organizations? *Dr Garfield* Yes, sir

Senator Pepper All right, Doctor, go ahead

Dr Garfield It has been Mr Kaiser's policy to create on each job that he has, where those facilities do not exist, a complete medical service which includes a hospital, medical service during sickness, and so forth The two areas that we have now that are critical areas are Richmond and Vancouver, Washington At Richmond—

Senator Pepper (interposing) Richmond California? *Dr Garfield* Yes, sir At Richmond, where we employ

men Mr Kaiser has caused to be built a hospital of 130 beds at his own expense, in the city of Oakland We have staffed the hospital with 36 physicians Let me first state that there is no shortage of physicians in our yards at the present time, that is, the Vancouver or Richmond yards Also in the Richmond area we have caused to be built right at the shipyards another hospital of 65 beds, completely equipped with surgeons and everything you need to care for these men Up in Vancouver where we now have 22,000 men and anticipate 50,000 men, we have another hospital erected, of 70 beds at the present time We have 18 physicians, nurses and all the necessary staff to operate it

Now in selecting our staff of these shipyard hospitals, as much as possible we have chosen men who we figured the Army or Navy would not accept Of our 36 doctors at Richmond, 12 are over 40 years of age 14 have physical defects for which the Army has rejected them, and about 13 are healthy, active men 13 out of 36 At Vancouver—

Senator Pepper (interposing) And young are they young men also? *Dr Garfield* These 13 are all in their 30s—pardon me, 2 are 40

Senator Pepper Are they married? *Dr Garfield* Yes, sir, every 1 of them is married. Now our particular problem is this—the Procurement Board in the Richmond area—

Senator Pepper (interposing) You mean the Procurement and Assignment Board, of which Dr Lahcy is the chairman? *Dr Garfield* Yes, sir

Senator Pepper Acting under the War Manpower Commission? *Dr Garfield* That is right. We have two particular problems. One is in Richmond and one in Vancouver, and they are different. The Procurement and Assignment Board in the Richmond area is not sympathetic with our program.

Senator Pepper You mean your program of keeping your workers healthy? *Dr Garfield* That is right.

Senator Pepper And providing for their medical care? *Dr Garfield* That is right. Our program not only includes for their accidents, but it also includes care for their health, nonindustrial illness, on a prepayment—

Senator Pepper (interposing) You mean you try to provide in your medical facilities medical attention whether the cause for it ensued directly from their work or from general conditions? *Dr Garfield* Yes, sir, it is a complete program. We know that 90 per cent of absenteeism due to illness is due to nonindustrial illness and it is our job to cut that down to get maximum production. The only way we know of doing that is—

Senator Pepper (interposing) By "nonindustrial illness" you mean illness attributable to causes not directly connected with their work? *Dr Garfield* That is right. The Procurement and Assignment Board, as I stated, are not sympathetic with that program. The Medical Association in general hasn't liked our doing prepaid medicine.

Mr Kaiser Although they can't serve it, they haven't the facilities to serve us at all.

Senator Pepper Go into a little detail on that. What do you mean by that, Doctor? You don't mean that they are not in favor of people being healthy, do you? *Dr Garfield* No, they aren't in favor of our coming into that area and taking over the care of those men. Incidentally, we didn't do it in Richmond—

Senator Pepper (interposing) Did you coerce this plan upon these people? *Dr Garfield* No, it is purely voluntary.

Senator Pepper Were these American citizens that you were giving this attention to? *Dr Garfield* Yes, and it is purely voluntary.

Senator Pepper And did they concur in the plan that was prepared for their benefit? *Dr Garfield* They are all signing up for it.

Mr Kaiser I would like to say this, in that connection so as to make it clear. It is purely a voluntary service on the part of the men, and unfortunately, because of the tremendous investment needed, I haven't had the necessary money to provide the facilities as rapidly as the men have asked for this, and we have shut off taking—in one area 39,000 have applied and we have been forced to stop taking the men because of the fact that we didn't have sufficient facilities to take care of them.

Senator Pepper What does the man himself do to get the benefit of this? *Mr Kaiser* He pays 50 cents a week.

Senator Pepper That goes into a fund? *Mr Kaiser* That goes into a foundation.

Senator Pepper Well now, do you supplement those funds or does management supplement those funds any, Mr Kaiser? *Mr Kaiser* I started and built the facilities, and furnished them as a foundation.

Senator Pepper And then the fees that the men pay, or the employees pay, are essentially for operating expenses? *Mr Kaiser* Yes, and we are extending—any that is left over is used as a foundation. At the present moment we are anticipating those fees and borrowing additional money to expand the facilities so we can take on more men.

Senator Pepper I was curious about your remark, Doctor, did you attempt to employ physicians and doctors and nurses who were of disrepute in the medical profession or incompetent? Was that the reason the medical association did not sympathize with your effort? *Dr Garfield* Oh, no, the history of the Medical Association—you know what happened here in Washington on the group medical prepayment basis—the medical profession naturally reacts to something like that in a contrary manner, they don't like prepaid medicine. Now as far as we are concerned, it is the only way we know, and we put it up to them before we started it, we told them we were going to do it and asked them if there was any other solution. It is the only way we know of taking care of those men adequately.

Senator Pepper As a doctor, have you any reason to suggest as to why the medical association as such, is opposed to

what you call the prepaid medicine? *Dr Garfield* Well, it is just a change in the old traditional way of handling medicine.

Senator Pepper The doctors that are working for you in your hospitals under the Kaiser organization and the nurses employed there, they are American citizens too, are they not? *Dr Garfield* Certainly.

Senator Pepper Did they come voluntarily? *Dr Garfield* We have a few aliens we have taken on, as far as doctors go.

Senator Pepper Those are some of the refugee doctors? *Dr Garfield* That is right.

Senator Pepper But essentially it was a voluntary process, these doctors and nurses coming into your institution? *Dr Garfield* Oh, yes.

Senator Pepper You pay them a fair compensation, do you? *Dr Garfield* Yes, sir.

Senator Pepper Which is satisfactory to them? *Dr Garfield* Yes, sir.

Senator Pepper And they are men and women of professional repute and personal integrity? *Dr Garfield* Yes, sir.

Senator Pepper So that the patients themselves come voluntarily into this association? *Dr Garfield* Yes.

Senator Pepper The technical staff comes voluntarily into the association? *Dr Garfield* Yes.

Senator Pepper And so does the management of the company in the provision of the foundation facilities? *Dr Garfield* Yes, sir.

Senator Pepper So that all the people directly concerned, so far as you know, are satisfied with the arrangement? *Dr Garfield* That is right.

Mr Kaiser Senator, this would be very interesting to you, since you were at Grand Coulee. At Grand Coulee we went further than the men themselves, we also went to the families and took on the health of the families, and in the early stages,—all through the whole stage it is voluntary, please believe that—in the early stages we only got those families that were very sick, and it was not at all profitable, in fact it looked like a loss—is that correct, Doctor? *Dr Garfield* Yes.

Mr Kaiser And we only had about 10 per cent. And then suddenly, as the result of the service to the families, voluntarily it increased to 90 per cent, and when we finished Coulee Dam we had 90 per cent of the families. And, Doctor, you can say how the deaths decreased. This is interesting.

Dr Garfield The most amazing part of the whole thing was that when we had the plan started and in operation, people stopped dying. That sounds funny, but actually what it meant was that they came to us,—

Senator Pepper You don't mean that the American Medical Association opposed a plan which made it possible for people to stop dying, do you? (Laughter)

Mr Kaiser This is interesting.

Dr Garfield Nobody opposed us up there because we were there alone. There were no other doctors and no other hospitals, and they let us alone. The reason they stopped dying was the fact that they would come to us with their early symptoms. There wasn't the factor of medical cost to keep them away. They would come to us with the first pain in their abdomen, when they first got their colds, and we would catch their appendicitis cases before they ruptured, would get the pneumonia cases before they were terminal, and we would take care of them and get them well. It really was amazing. It is the one thing that struck us and we are sold on it. Financially we believe we lost money on the operation up there but as far as that reflects on their health it was tremendous.

Senator Pepper Now, Doctor, this is what lawyers would call a conclusion and a question of an expert, but since you have had this experience and since you are a doctor, I think you would qualify in any court to be able to answer this question. Is it your opinion, based on your experience in this place and other places where this plan has been put into effect, that a number of human lives have been saved by the operation of this plan which could not have been saved by the operation of the ordinary system of private medical care paid by your own funds in the normal way? *Dr Garfield* There is no question about that. I am afraid we are making too much of an issue out of this in relation to our problem. Now the Procurement and Assignment Board hasn't come out and said 'Now we don't like you because you are doing this, and we are going to take your doctors away,' but indirectly there is that sort of a feeling in the situation. In other words, they are not sympathetic with what we are doing and I think they are not sympathetic with keeping our organization going. Now they have asked me to replace all our doctors with older men. We have 11 doctors down in the Richmond area who are over 40, 50 and some as high as 65. Those men can do a limited amount of work. They aren't active any more, they have to sit in one

spot. We have a tremendous volume of work taking care of — men both industrial and nonindustrial, and it is a job. We need a certain number of young, active men to do that work, particularly our specialists. When we create this service, we build it around a specialist group, surgeons, orthopedic men, eye, ear, nose and throat, to give the men the best possible service.

Senator Pepper In other words, in any kind of an efficient medical organization which is comprehensive in character, there are a few key men, and if you take those key men out you break down the strength of the organization? *Dr Garfield* That is right.

Senator Pepper You say they want to take those key men away from you? *Dr Garfield* They have asked us to replace all the men who are available for army service.

Senator Pepper As a matter of fact, the job those key men are doing is to keep men working in the shipyards and in the other war work that the Kaiser company is doing? *Dr Garfield* That is all they are doing.

Senator Pepper So they are contributing essential things necessary to the carrying on of the war? *Dr Garfield* That is right and they are doing it this way—one doctor to 2,000 men. Now the Army according to what Mr McNutt told us the other day has 40,000 doctors to 4½ million men, approximately. That is 1 to 100. We are doing it with 1 to 2,000. Not only that, but we are taking care of all the sick men—all the men that the Army didn't take. We have no physical examinations on our job, that is a union demand and even if it wasn't a union demand we would have to keep everybody working we possibly could. We are taking care of men on those jobs—some of them have cancer and they are physically unfit all sorts of conditions, but we are keeping them working.

Mr Kaiser Senator, the Doctor is bringing out a point that is very important and he is bringing out this point—that in the Army we have one doctor to each hundred men where in the Army of Supply the men who are producing the things that those men need in the field to be protected we only have 1 to 2,000. It is a problem worthy of a lot of consideration and I don't know what the answer is but it should be known that that problem exists.

Senator Pepper At least, Mr Kaiser, if your suggestion were adopted and there were an overall Manpower Committee—Mr Kaiser (interposing) That is the answer.

Senator Pepper (continuing) —the same committee that procured doctors for the armed services would be concerned about the procurement of doctors for this Army of Supply? *Mr Kaiser* Yes, the whole thing is all one problem.

Senator Pepper In other words, while the Army is telling you that you must let them have all your young men, you might say to the Army 'You must take some of our older men'? *Mr Kaiser* That is right. And Dr Garfield's position is that with the medical society practically directing and handling the Procurement Service if they are not in sympathy with our prepaid medical service—which some of them are and some of them are not, that is clear to every one—but if they are not, they are not the ones in any case to direct a service of this kind or to be associated with it. There could be prejudice and it shouldn't be there.

Senator Pepper Do I understand, then, from you Mr Kaiser, and you, Doctor, that although the present Procurement and Assignment organization under the Manpower Commission occupies on its surface an official status nevertheless you find, or you believe that it represents essentially the views of the American Medical Association in its policies? *Dr Garfield* I don't think there is any question about that, and fundamentally they are doing a good job. They don't realize the importance of production, they haven't come over from San Francisco to Oakland to see our shipyards, they don't know what we are doing. I have told them, but that is about as far as it goes. We need somebody in back of it who is primarily interested in what we are doing.

Mr Kaiser Senator Pepper, I think it is only fair to say that I went to see Dr Lahey. Dr Lahey understands this problem, I couldn't imagine a man who could be more devoted and more sincere and with greater leadership, and a very fine individual, but he nevertheless is only one man, and he doesn't control, it is the system that you are concerned with.

Senator Pepper That is just what I was going to suggest, Mr Kaiser. Dr Lahey came before our committee a few days ago, and the Doctor exhibited all those fine qualities you have mentioned. Moreover, he exhibited that he was practically an automaton—I say it without deprecation—a marionette for the procurement people in the Army and Navy,

they just said, "We want so many doctors," and it was their job to go out and get so many doctors. They did decide sometimes, through the recommendations of the medical association or as a result of a survey, the people in a given community who were eligible to come in, who are essential or nonessential, but essentially there wasn't any agency at the top who was dividing the nation's medical manpower between the Services of Supply and the fighting services, that is, the services that were nearer the front line of battle, and that is why you are suggesting the necessity of the overall consideration of this problem? *Mr Kaiser* That is right.

Dr Garfield Let me mention our Vancouver problem. It isn't so long. Up there the Procurement and Assignment Service are very sympathetic with our program, they backed us 100 per cent, every doctor we have they said 'You can keep'. But they do one thing which stops us, they say to us 'You cannot take care of anybody but your employees.' Now Vancouver is an area of 18,000 people. In connection with our shipyard workers Mr Kaiser has caused to have built about 15,000 family units in the area, and bring into those units about 50,000 people. With the men in our wards, there will be an increase of population from 18,000 to 100,000 people in that area. The Procurement and Assignment Board tells us 'Your men are O. K. working at the yards taking care of your employees but you must not take care of those families. If you do, we will declare your men nonessential and they will be taken into the Army.'

Senator Pepper Who told you that? *Dr Garfield* The director of the State Procurement Service. I have a letter to that effect.

Senator Pepper Under the National Procurement and Assignment Service headed by Dr Lahey, in the Manpower Commission? *Dr Garfield* Yes, sir.

Senator Pepper So they told you it you allowed your medical staff to give medical attention to the families of your workers in the same community in which your operations were carried on, that they would punish you by declaring your doctors that were serving these people nonessential, and put them into the Army? *Dr Garfield* Yes, sir, we have a letter to that effect.

Senator Pepper Is that letter available so that you could allow us to have it? *Dr Garfield* I have a copy of the letter here.

Senator Pepper We would like to have it. You just read it, Doctor.

Mr Kaiser I want to continually impress on you that we are not here to criticize, we are here to work to help and to get some results.

Senator Pepper The thing you are interested in is efficient production for war? *Mr Kaiser* That is right, we are very seriously, and it is merely suggestions that we are offering. It is very easy to be selfish, and we don't want to be that way.

Senator Pepper Do you find it, Doctor? *Dr Garfield* Yes. It is written by the chairman of the Procurement and Assignment Service.

Senator Pepper Go right ahead. *Dr Garfield* Do you want the whole letter or the part pertinent to this particular thing?

Senator Pepper That is all right.

Dr Garfield (reading)

Employees Family Care. That no prepayment plan shall be adopted for the care of the employees dependents. Further that such dependents may have all the facilities of the company hospital under the care of physicians of their choice. The company reserves the right of staff supervision. The company is our medical service. That no full time physician who is an employee of the company shall treat such dependents except in an emergency. This plan shall be effective until local medical care shall become insufficient or unforeseen exigencies arise demanding reconsideration.

Now they don't threaten us there, but that is what they told us in that meeting.

Senator Pepper They orally told you that you would have these men classified as eligible for armed service and brought into the armed service if you violated the instructions they gave you here of confining their medical attention to your employees only, except in cases of emergency? *Dr Garfield* Yes. Now incidentally, that would be satisfactory with us we are not anxious to go out into the field of taking care of those families.

Mr Kaiser We haven't the facilities.

Dr Garfield But there are only 15 doctors in Vancouver. At the present time there are about 40,000 people there, and it is going to be increased to 100,000. Those doctors are working at capacity now. Now all these people coming into that area are going to need medical attention, and it is going to reflect on our job.

Senator Pepper Doctor, what I can't understand is, you said that that letter was from the chairman of the Procurement and Assignment Service for doctors in Vancouver, or in the state of Washington? *Dr Garfield* The state of Washington.

Senator Pepper Acting under the National Procurement and Assignment Service in the War Manpower Commission? *Dr Garfield* Yes, sir.

Senator Pepper What I can't understand is why that agency has the slightest concern about whether any prepayment plan or anything like that is adopted. Has the Manpower Commission adopted any policy on prepayment plans for medical attention for the civilian population? *Dr Garfield* They are using this Procurement and Assignment Service to take care of things that they don't like.

Senator Pepper You mean who doesn't like? *Dr Garfield* That the medical society doesn't like.

Senator Pepper What connection has the medical society got with this problem? I thought that was from the chairman of the Procurement and Assignment Committee for doctors in the state of Washington. *Dr Garfield* Well, he is a doctor of the medical society.

Senator Pepper He is what? *Dr Garfield* You see, the Procurement and Assignment Service are composed of medical men of the Medical Society of Washington.

Senator Pepper Does this chairman of the Procurement and Assignment Service have any official position in any of the medical societies? *Dr Garfield* He is chairman of the state medical society.

Senator Pepper Oh, he is also chairman of the state medical society? *Dr Garfield* That is right.

Senator Pepper So the same man who is supposed to represent the United States of America in the procurement of doctors for the service of the Army and Navy, is also the state chairman of the medical society, which is a local branch of the American Medical Society? *Dr Garfield* Yes, sir.

Senator Pepper So he takes advantage of his position as a public official to effectuate the policy of his private medical association is that correct? *Dr Garfield* That is right.

Senator Pepper So the relationship, then, between the Procurement and Assignment Service of the War Manpower Commission, and the private organization of private professional men, known as the American Medical Association, is very intimate? *Dr Garfield* Well, they are the same thing.

Senator Pepper So that public policy emanates primarily from a private source in many respects, according to your experience, in the procurement of doctors? *Dr Garfield* Yes. I don't want this to be interpreted as an attack on the medical society, it isn't. But they are stopping us from doing something that is very necessary in that area, and which bothers us quite a bit.

Senator Pepper And which has a directly injurious effect upon the health and the lives of American citizens, primarily women and children, the families of war workers in the area that you have described? *Dr Garfield* There is no question that it will have. We have the medical staff there to do the job, and people come to us for medical care and we can't take care of them, we are not allowed to, we call doctors from Vancouver to do it, and they are too busy to do it.

Dr Lamb In that connection, Doctor, this great increase in the population of Vancouver will be the families of your workers? *Dr Garfield* Yes, sir.

Dr Lamb For the most part? *Dr Garfield* Those housing facilities were built for our people.

Dr Lamb Specifically for them? *Dr Garfield* Yes.

Dr Lamb So that the health conditions in those dwellings will be the health conditions of the families of your workers? *Dr Garfield* Surely.

Dr Lamb And what happens to those families will directly affect the worker on the job? *Dr Garfield* It goes further than that. If we should have an epidemic in that housing area, it might stop our job. If we had to quarantine that area, it would stop our job and stop production, it is really a dangerous, critical situation.

Dr Lamb And one for which, as the expansion takes place, there are no facilities in sight? *Dr Garfield* No facilities. Now we could provide for it, and that is what we want to do, but we are stopped by this order of the medical society. Now I haven't gone back to them and argued the thing more, which I should have done. This thing happened fast, and the only reason I am here—I didn't know I was going to be here—but I might go back there and by arguing with them and talking them into it, I might turn them around to our viewpoint, but it would be quite a job because the local medical society does not want us to have anything to do with the medical care of

those people. Now they are not equipped to do it, they haven't got the time and they are all busy now. But still they want us to stay out of the picture.

Mr Kaiser They haven't any hospitals to do it in. *Dr Garfield* The hospitals there are all filled up.

Senator Pepper So from what I understand you to say, the medical society would rather the women and children who are the families of the war workers in the Kaiser yards in that area, building ships for the United States of America, would go without medical care and attention than that they should receive it through the facilities that you have described? *Dr Garfield* Well, no, they don't say that, they say they will take care of it somehow.

Senator Pepper Do they have the facilities? *Dr Garfield* No.

Senator Pepper So then what I said is substantially the fact, whether it is the intent or not of the society? *Dr Garfield* Yes.

Senator Pepper In other words if you don't furnish this service to them, it is not available. Yet they don't want you to furnish it? *Dr Garfield* That is right.

Mr Kaiser The best illustration is that the population has more than doubled, and there have been no increased facilities and therefore there is that situation.

Dr Garfield There are fewer doctors there than there were five months ago, and no hospital facilities have been added except the ones we built.

Senator Pepper Doctor, what you say strikes me with particular force, because I have heard it hurled as a criticism against some so called new dealers in the government that they were trying to advance social gains as a part of the war effort under the cloak of the war. From what you have said, it looks to me as if there may be some who have tried to protect special interests under the cloak of the war too. *Dr Garfield* Right.

Senator Pepper I wanted to ask you, Mr Kaiser, from what you have said, and from your vast experience, whether it would be proper to say that health is a military necessity, that health is necessary to the war effort? *Mr Kaiser* There isn't any question but what it is, absolutely. We have thought so before the war, best illustrated by what we have done in the way of hospital facilities and care of the men, and we are going on with that after the war, we are going to continually do this thing, because we believe that this will be of benefit to the medical association, because we believe that our people should become medically conscious, and when they do there is opportunity for any one, privately or otherwise. We do not believe that should be a government service, we believe that should be an industrial service created by the industrialists who are responsible for employing those men.

Senator Pepper In other words, Mr Kaiser, you believe that the doctors would not suffer by health facilities being extended to a larger number of people, because there would be a greater demand for doctors? *Mr Kaiser* That is exactly what I believe but I believe more forcibly that that isn't anywhere near as important as it is to the United States of America that the industrialists who are responsible for the industry of this country take care of those men and provide them with the facilities and give them the opportunity to join with them voluntarily. Unquestionably it should be a foundation and not a profitable institution, it should be a foundation created by industry that should go on and on and be a perpetual care of every man that is employed—and that is my ambition. But it involves a great deal of investment and can only be done gradually. But now that we are in this thing as we are and it is a war supply service, it is of vital importance, and therefore it is of vital importance that the medical association or every man in America recognize its vital importance. The question is if it is not as important to serve the supply lines as it is to do the fighting, because if those men are left without service, they can not do any fighting.

Dr Lamb First a question, Mr Kaiser, about this medical care program that you have described. Would you say—I got the impression from something you said earlier that you would say that, once this program was known to the workers and had begun to roll, the voluntary prepayment plan would build up in such a way that it would ultimately be on not a profit making basis, but a balanced budget basis? *Mr Kaiser* That is right.

Dr Lamb So that any possibility that at Grand Coulee you had originally lost money, was due to the small participation? *Mr Kaiser* That is right, that was early, the total service finally came out all right. That was not a foundation. Now I am going ahead with a foundation so that any returns are immediately going to the advancement of that service.

[Here was a considerable discussion of the proposal of Mr Kaiser on control of manpower. Next Senator Pepper called for Dr Morris Fishbein.]

Dr Fishbein Would it be amiss to ask that Dr Garfield remain while I correct some facts and so that he may correct me if I am wrong as to certain statements he made?

Senator Pepper This is not a debating society between you and Dr Garfield, but if he cares to remain we would be glad to have him.

Dr Fishbein I understand that.

Senator Pepper Will you state your name?

STATEMENT OF DR MORRIS FISHBEIN

Editor THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Dr Fishbein Dr Morris Fishbein

Senator Pepper Where do you live, Doctor? *Dr Fishbein* Chicago

Senator Pepper Where did you receive your medical education? *Dr Fishbein* The University of Chicago and the Rush Medical College, Chicago

Senator Pepper How long have you been engaged in the practice of medicine? *Dr Fishbein* Following my graduation I was about a year and a half in practice and in research on pathology

Senator Pepper You are not now engaged in the practice of medicine? *Dr Fishbein* No sir

Senator Pepper What is your employment at the present time? *Dr Fishbein* I am editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and of *Hygeia* a health magazine. I also am professorial lecturer at the University of Chicago School of Medicine and the University of Illinois

Senator Pepper What are the subjects of your lectures? *Dr Fishbein* Medical economics and history of medicine

Senator Pepper They are not technical subjects? *Dr Fishbein* Not the practice of medicine

Senator Pepper How long have you held your present position? *Dr Fishbein* I have been editor since 1924 and was assistant editor from the end of 1913 up to 1924

Senator Pepper In what manner were you chosen for your present position? *Dr Fishbein* I was chosen by the Board of Trustees of the American Medical Association which is the body elected by the House of Delegates to administer its affairs

Senator Pepper Will you give us a brief summary as to the nature of the organization known as the American Medical Association, the number who are in it and what its organizational setup is, Doctor? *Dr Fishbein* The American Medical Association is a voluntary membership organization. There are in the United States about 176,000 doctors licensed to practice. There are 123,000, approximately, who are members of the American Medical Association. These members are organized into county medical societies, which in turn are organized into state medical societies. The county medical societies elect delegates to the state medical associations and the House of Delegates of each of the state associations elects delegates to the House of Delegates of the American Medical Association. The House of Delegates of the American Medical Association is the body charged with establishing all policies of the American Medical Association

Senator Pepper Do you have annual conventions? *Dr Fishbein* There is an annual convention of the House of Delegates and of the organization and, in addition to that, special meetings when called for

Senator Pepper That annual convention embraces which House of Delegates, the national house? *Dr Fishbein* The national House of Delegates

Senator Pepper The one that is elected by the states? *Dr Fishbein* By the state houses of delegates

Senator Pepper And the national House of Delegates selects a Board of Trustees? *Dr Fishbein* The national House of Delegates selects a Board of Trustees

Senator Pepper How many are there on that Board? *Dr Fishbein* There are nine members of the Board of Trustees. Two are elected each year to serve a term of five years, and the maximum term is ten years for any trustee

Senator Pepper You are employed, then, by the Board of Trustees? *Dr Fishbein* I am employed by the Board of Trustees

Senator Pepper Do you have a national headquarters of the Association? *Dr Fishbein* The National Headquarters is in Chicago

Senator Pepper How much of a clerical and managerial staff is employed? *Dr Fishbein* We employ from 630 to 640 people

Senator Pepper Are you considered the executive director of the organizational setup of the Association? *Dr Fishbein* No, sir, the Association is organized with a Secretary and General Manager, who is the executive director. That is Dr West. I am the editor in charge of publications

Senator Pepper Who determines the public policy for the Association? *Dr Fishbein* The House of Delegates determines all policies, and the officials of the Association are charged with maintaining and extending to the profession the policies of the Association

Senator Pepper Do you sit in with the group which determines the policies of the Association? *Dr Fishbein* I have no voice in the House of Delegates except when called to give information

Senator Pepper As a practical matter do you consult with the members of this body in the formation of policies? *Dr Fishbein* I may appear before any committee. All actions of the House of Delegates are taken by setting up a reference committee which hears the proposed action and any member of the Association may appear before any reference committee. The reference committee brings back its report to the House, and then the House acts on the report of the reference committee, after debate

Senator Pepper As a practical day by day matter, the articulation of the policy occurs primarily in the publication known as THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION? *Dr Fishbein* Yes

Senator Pepper Of which you are the editor? *Dr Fishbein* Yes sir

Senator Pepper So that you are the one who articulates these policies that are formed, you say by these authorities? *Dr Fishbein* Of course the proceedings of the House of Delegates are published broadcast to the medical profession and the nation as soon as an action is taken. The articulation of the policy is in the proceedings of the House of Delegates, which are published as a routine matter without modification

Senator Pepper How many times are those publications issued how many times is the action of the House of Delegates published? *Dr Fishbein* It is published at once when the action is taken, and then maybe it is published repeatedly if discussion is needed

Senator Pepper How many times per year is THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION published? *Dr Fishbein* Every week

Senator Pepper So the public gets a chance to see and hear the articulation of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION a great deal more than they hear what is uttered by the body which you refer to, does it not? *Dr Fishbein* That depends of course, on the importance of the policy in relationship to the public situation. At the last annual convention of the Association in Atlantic City there were in attendance representatives of every press association and important news paper in the country, so that the actions were widespread throughout the nation

Senator Pepper But the only weekly publication, the only regular periodical of the American Medical Association is THE JOURNAL, of which you are the editor? *Dr Fishbein* No, there is also another publication which is sent to all newspapers and press agencies throughout the country each week

Senator Pepper What is that? *Dr Fishbein* That is known as the *American Medical Association News*. So that all matters having to do with activities are sent out each week

Senator Pepper Who is the editor of that? *Dr Fishbein* A layman named Lawrence Siler

Senator Pepper Is his office in the headquarters of the Association in Chicago? *Dr Fishbein* Yes

Senator Pepper Is there any practical cooperation between you and him? *Dr Fishbein* He prepares the publication, and naturally it is approved by the Editor and the General Manager

Senator Pepper Which means you? *Dr Fishbein* And Dr West

Senator Pepper So as a matter of fact you are considered are you not Doctor, the able and eloquent voice of the American Medical Association? *Dr Fishbein* Well, that is not my term

Senator Pepper Maybe I should have said the pen instead of the voice? *Dr Fishbein* I prefer to be known as the editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Senator Pepper Ofttimes we cannot limit ourselves below the reputation that we have gained, Doctor. As a matter of fact do you make any public addresses? *Dr Fishbein* Many

Senator Pepper Roughly how many speeches do you make in the course of a year, would you say? *Dr Fishbein* About one hundred

Senator Pepper Does any other official of the American Medical Association make as many addresses? *Dr Fishbein* I would say that many of them make addresses. *Dr Bauer*, who is head of our Bureau of Health Education, makes perhaps sixty addresses a year.

Senator Pepper He speaks primarily about public health matters, more or less on technical subjects I would assume? *Dr Fishbein* He speaks on public health. Now each of our trustees makes addresses. I would say that on an average each trustee may speak from ten to twelve times a year.

Senator Pepper On matters of American Medical Association policy? *Dr Fishbein* Almost wholly on policy.

Senator Pepper But it would not do any disservice to the great contribution that you have made to the Medical Association would it, Doctor, to say that so far as the American public is concerned, and generally so far as the American Medical Association members are concerned you are the man, the official, the agency, through which the policies of the American Medical Association are regularly expressed in writing and in speech? *Dr Fishbein* That is correct, yes, sir.

Senator Pepper Now, Doctor, would you be good enough to tell us whether you are acquainted with the Assignment and Procurement Service or, rather, the Procurement and Assignment Service, which is set up under the War Manpower Commission? *Dr Fishbein* I am acquainted with that service.

Senator Pepper Who is the head of that? *Dr Fishbein* Dr Frank Lahey.

Senator Pepper He was at one time President of the American Medical Association, was he not? *Dr Fishbein* Yes, at the time he was appointed head of the Procurement and Assignment Board.

Senator Pepper He has some assistants? *Dr Fishbein* He has a board, including four other men.

Senator Pepper Are they members of the American Medical Association?

Dr Fishbein There are 123,000 members of the American Medical Association and it may almost be taken for granted that any physician of any repute at all is a member. These men are all members except Dr Camalier, who is on that board and is a member of the American Dental Association—C Willard Camalier.

Senator Pepper Did you have anything to do with Dr Lahey's selection as chairman of the Procurement and Assignment Board of the War Manpower Commission, for doctors? *Dr Fishbein* The establishment of the Procurement and Assignment Board—I can give you the complete story of it if you wish it is a little long—

Senator Pepper (interposing) Let me ask you this. Did you make any recommendations on the subject? *Dr Fishbein* I was one of some thirty men who made the recommendations of a group of men to the Coordinator of Health, Defense and Welfare.

Senator Pepper Who was that Coordinator? *Dr Fishbein* Mr McNutt.

Senator Pepper You recommended along with some other people, to Mr McNutt, that Dr Lahey be selected as chairman of this Procurement and Assignment Board? *Dr Fishbein* Yes, sir.

Senator Pepper At that time Dr Lahey was President of the American Medical Association? *Dr Fishbein* Yes, sir.

Senator Pepper And Dr Lahey accepted that responsibility and has occupied that position since that time? *Dr Fishbein* Yes, sir.

Senator Pepper Now Dr Fishbein, was a survey made of the doctors of the country by the American Medical Association? *Dr Fishbein* The American Medical Association established, about 1905, a regular system of keeping a record available of every physician in the United States including as well his record of graduation, his background after graduation, his preliminary education and a record of the deaths of physicians. That directory is published every two years. It is maintained as a going concern, so that week by week it is kept up to date. When, in June 1940, it appeared that we might be engaged in a war, the Surgeon Generals of the Army and the Navy asked the House of Delegates of the American Medical Association, at its meeting to make a study of the available manpower of the nation in the field of medicine in order to make certain that a rapidly expanding army and navy and industry, and the civilians of the country might be provided throughout the period of the emergency with adequate medical service. It was recognized at once that the demands of a large army would be considerable.

Senator Pepper You say "with adequate medical service." Did they ask you to decide also the question as to whether the country and the civilian and military population needed any more doctors than the country already had available? *Dr Fishbein* That question was to be included in the study, yes, sir. Immediately following that session a meeting was held with the Surgeon Generals of the Army and Navy and the Board of Trustees of the American Medical Association who set up a Committee on Medical Preparedness, which was to be charged with the function of preparing the medical profession for the emergency. In June 1940 therefore, plans were made to make a new and immediate survey of the entire medical profession of the country in order to determine how many physicians would be willing to volunteer at once for the armed forces in case of need since at that time obviously the only source of medical officers for the armed forces was voluntary enlistment. Then, when the Selective Service Act was passed, obviously there was another source for medical officers of the Army, namely those men included under Selective Service who were also physicians. Immediately the results of that survey were transferred to a punch card system, and that punch card system was established in the headquarters of the American Medical Association. On each punch card there are some eighty different points regarding each physician in the country, with regard to his availability for any of these services, the Army, the Navy, industrial medicine or civilian practice. When it became apparent that this problem was one of much larger scope than one that could be handled by any civilian organization, it was suggested that since the government had itself already established a National Roster of Scientific and Trained Personnel, which did not however include the data regarding the medical profession and the dental profession and the veterinarian profession, that the A M A turn over to the government its punch card system covering the doctors of the country. So a complete set of similar cards was made and presented to the National Roster of Scientific and Trained Personnel, which is now a part of the War Manpower Commission.

Senator Pepper Who made up the Roster of Scientific and Trained Personnel other than the doctors—*Dr Fishbein* (interposing) That was made up, I believe originally, as a part of the National Resources Planning Board.

Senator Pepper It was made by a public agency? *Dr Fishbein* By the government.

Senator Pepper But in the case of the doctors the Roster was prepared by the doctors themselves?

Dr Fishbein Well, I will proceed now. The original inventory was prepared by the doctors themselves and it was decided to turn this over and our cards were copied completely and turned over to the National Roster of Scientific and Trained Personnel. By that time, however, we were already in the war and there had been considerable shifts of population and of the medical profession. I would say that by that time already at least 20,000 physicians had gone into the armed forces. So a new questionnaire was prepared by the Procurement and Assignment Service, working with the National Roster for Scientific and Trained Personnel. That new questionnaire, which was developed by them, was then sent again to every doctor and dentist in the United States and to the veterinarians and they now have the two sets. They have the original set and they have the newer inventory which was made in 1942.

Senator Pepper That last questionnaire is not the one which Dr Lahey referred to as the one which was accompanied by a very strong intimation that if they didn't come in as the Procurement and Assignment Service suggested their names would be turned over to the Selective Service, was it?

Dr Fishbein That intimation, of course is implicit in the Selective Service Act and need not be an intimation. Every man in the United States under 45 years of age is subject to Selective Service, so it is not necessary for the medical profession or any one to turn over their names to Selective Service.

Senator Pepper But if I understood Dr Lahey correctly, at the time the Procurement and Assignment Board sent out the call for the doctors that they regarded as nonessential, to come in, they also sent a copy of that call to Selective Service authorities, which gave a very strong suggestion to the recipients of the Board of Procurement and Assignment's message that if they didn't comply with its direction there would be coercion applied to them by the Selective Service authorities, is that right? *Dr Fishbein* I happen to have seen the statements sent by Selective Service to the Selective Ser-

vice Boards, and I happen to have seen also the letters sent by Procurement and Assignment to individual physicians, and I would not have said that there was coercion.

Senator Pepper You mean that you have been working intimately with the Selective Service authorities in the procurement of doctors? *Dr Fishbein* No.

Senator Pepper How did you happen to see these letters?

Dr Fishbein There are 28,000 doctors contributing their services to the Selective Service Boards, and these facts are available to every one. You can go into any Selective Service board or appeal board and see the memoranda sent by Selective Service.

Senator Pepper You saw these directives in the headquarters of Selective Service? *Dr Fishbein* I have seen such directives in the headquarters of Selective Service. There is also a medical department of Selective Service headed by Colonel Rountree.

Senator Pepper Do you have any official position in that medical department of Selective Service? *Dr Fishbein* No, sir.

Senator Pepper But by reason of your prominence in the medical profession and your responsible place in the direction and expression of policy for the American Medical Association, you have had an intimate relationship with these medical authorities in the Selective Service system? *Dr Fishbein* I would say that primarily as an active journalist I see pretty nearly everything that I can see that would interest the readers of the magazine.

Senator Pepper I wonder if other publishers of magazines are given the same entree to the records of the Selective Service System? *Dr Fishbein* I have not seen the records of the Selective Service System, I have seen the memoranda issued to local boards and appeal boards, which are generally published widely.

Senator Pepper I wonder if other personnel in Selective Service headquarters is kept in as intimate touch with their professional connections in the country as the medical authorities appear to have kept you informed as to what was of medical significance? *Dr Fishbein* I should think so. I have sat in at a meeting of the American Council on Education, and I happen to know that the engineers of the country and the architects—all trained personnel—are well in touch with the plans regarding the procurement of trained personnel. That is obviously necessary, since you begin in the grade school to prepare men for trained positions.

Senator Pepper I was wondering whether or not you would say that because of your influence, or rather your association with these medical authorities in the Selective Service System, that you or the American Medical Association has had any material influence on the policy of the government with respect to the procurement of doctors? *Dr Fishbein* I would say only as far as we have published our opinions and they have listened to them.

Senator Pepper Does the Board of Procurement and Assignment have doctors acting under the Manpower Commission of any state organization? *Dr Fishbein* They have an organization not only in each state but in each corps area.

Senator Pepper Who constitutes the head of the state organization? *Dr Fishbein* In each state the Procurement and Assignment Board itself selected its own state representative, those vary in different states.

Senator Pepper As a matter of fact do you know any of the heads of the state boards and know whether or not they have any connection with the state medical associations?

Dr Fishbein I would say that some do and some don't. The endeavor was I believe, to find in each instance a doctor who was of sufficient age so that he himself would not be called into the military service, because the medical profession has viewed the problem as being first the supplying of the armed forces with the physicians necessary to meet the needs of troops in camp, in training and in combat.

Senator Pepper Who was it that had that idea? *Dr Fishbein* That idea was the general idea of the medical profession as a whole. The original policy adopted by the House of Delegates stated that.

Senator Pepper Did I understand you? When you speak of the plan of the American Medical Association or of the medical authorities for furnishing medical facilities to the armed services, are you talking about some agency other than the government deciding how it would use its medical personnel? *Dr Fishbein* No, sir, we have no authority over medical personnel. The A M A has no authority and the Procurement and Assignment Service has no authority, the authority rests with the local boards.

Senator Pepper The chairman of the Procurement and Assignment Board at the time of his selection was President of the American Medical Association? *Dr Fishbein* Yes, sir.

Senator Pepper Could you tell us in how many states the head of the Procurement and Assignment Board was, at the time of his selection, or is now, head of the medical society for that particular state? *Dr Fishbein* I would say that in a small proportion the smallest proportion, it was the president. In some instances it was the chairman of the council, in some instances it was the secretary, in some instances it was the chairman of the committee on medical preparedness of the state medical society and in some instances it was a physician who was merely known to be the best physician available for the position.

Senator Pepper In how many states would you say, from your intimate acquaintance with the organization of the state societies, it was true that some official of the state medical society was the state head of the Procurement and Assignment Service? *Dr Fishbein* Well, does that go down to committee appointments also in the state?

Senator Pepper You know, Doctor, what I am getting at. *Dr Fishbein* We have the state president, the state vice president, the secretary of the state medical society, the council of the state medical society, the house of delegates of the state medical society with its chairman. Then we have innumerable committees, including committee on medical preparedness of the state medical society. I would say that in practically every instance—well, not every because I could name possibly five where the man had held no position in the state society—but let's say that in forty-three states the man had a relationship to the state medical society.

Senator Pepper Now Doctor, as a matter of fact—it is a fact, is it not—that in setting up its Procurement and Assignment Service the United States government essentially took over the organization of the American Medical Association?

Dr Fishbein No, that would not be true.

Senator Pepper Well, they took over the President of the American Medical Association? *Dr Fishbein* But we change our president every year.

Senator Pepper And they took over in the states some official or some prominent committee member of the A M A to be the head of the state Procurement and Assignment Service for doctors? *Dr Fishbein* That would have to be coupled with the statement that practically every reputable doctor in the United States is a member of the American Medical Association.

Senator Pepper I didn't ask you whether they took over members or not. In the case of Dr Leahy they took the President of the American Medical Association? *Dr Fishbein* Yes, sir.

Senator Pepper And you have already told us that in several states they took over generally—there may have been an exception in five states—but in at least forty-three of the forty-eight states they took over one of the officials, one of the prominent officials of the state medical society, or one of the prominent committee chairmen, as head of the state Procurement and Assignment Service? *Dr Fishbein* That would be correct usually the chairman of the committee on medical preparedness in that state.

Senator Pepper So that all the men who have been active in the functioning of the Procurement and Assignment Service—or most of them—have been active in the affairs of the American Medical Association? *Dr Fishbein* Well, of course that is a question which is very difficult to answer, when you say "all." If you would say "most of the men," I would say yes.

Senator Pepper Now then Doctor, Dr Leahy I believe further testified to us that the quotas were turned over to them by the armed services and—*Dr Fishbein* (interposing) The armed services stated to them their need for physicians.

Senator Pepper And they went out to get the personnel that the armed services required? *Dr Fishbein* Yes, sir.

Senator Pepper Now you have heard the statement made here this morning that Mr McNutt had stated that we had in the armed services essentially 1 doctor for each 100 men—is that statistically correct? *Dr Fishbein* The Army endeavors to secure 65 doctors per thousand men. Of course if you take the Army and the Navy together, we have, I believe, to give a round number because we are not supposed, I believe, to give exact figures, something over 40,000 doctors in the armed forces at this time.

Senator Pepper Well now, Doctor, did any authority, representing the needs of the civilian population of this United States for health attention, sit in at the time those quotas were made and those directives were issued? *Dr Fishbein* The quotas of the Army?

Senator Pepper Yes—to consider what the needs of the civilian population were? *Dr Fishbein* As far as I know, no civilian has endeavored, in the field of medicine, to tell the Army what their needs were.

Senator Pepper Obviously the taking of doctors from the country will affect the public health, will it not? *Dr Fishbein* Yes, sir

Senator Pepper You regard the doctors and the nurses, of course, as essential to the maintenance of the public health?

Dr Fishbein Yes, sir

Senator Pepper So that it is almost possible to say that in the fixing of the quotas for the armed services, the public health—thinking of the health of the civilian population—was not considered? *Dr Fishbein* No, it would not be possible to say that because after all the Procurement and Assignment Service was charged by the President in his directive, with the conservation of civilian health, of industrial health and of the health of the armed forces

Senator Pepper Do you know of any instance, Doctor, where the Procurement and Assignment Board turned down any request for a quota that was issued to them in the form of a directive or request by the armed services? *Dr Fishbein* I would say rather that the Procurement and Assignment Service approached the matter scientifically—

Senator Pepper (interposing) Will you excuse me—I am trying to get an answer to my question Did they turn down any request made by the armed services? *Dr Fishbein* I would say that in certain instances when the armed services had requested a man, they had refused to release that man, having declared him essential for civilian health That has happened many times

Senator Pepper Well, the armed services never did tell them what man to call in as an individual, so Dr Lahey testified? *Dr Fishbein* Oh yes, because men enlist voluntarily and the man who enlists voluntarily is cleared through the Procurement and Assignment Service just as well as the man who is drawn in by his draft board

Senator Pepper Now in the state of South Carolina, if I recall correctly the testimony of Dr Lahey, there has been a survey made and a quota established as to the number of doctors that could be taken from that state *Dr Fishbein* Yes, sir

Senator Pepper And that was being handled on a statewide average by 1 doctor to every 4,100 people *Dr Fishbein* That is a little tall, but I have the exact figures and I can leave them here

Senator Pepper And the quota that was established for that state was, by the various means by which doctors were taken into the armed services, after a while 170 per cent *Dr Fishbein* Yes, sir

Senator Pepper So that in a state which already had a deficiency of doctors the existing system allowed 70 per cent more doctors to go into the armed services and out of the civilian population than the American Medical Association had said was the quota for that state, isn't that a fact? *Dr Fishbein* Well, let's get that straight again

Senator Pepper Is that or is that not a fact? *Dr Fishbein* That is not a fact The American Medical Association had nothing whatever to do in any way, shape, manner or form with establishing quotas for anything

Senator Pepper Did the Procurement and Assignment Service make up those quotas? *Dr Fishbein* The Procurement and Assignment Service decided of itself, and without any consultation with the American Medical Association, that they wished to set for this year a minimum of 1 doctor to each 1,500 people remaining in the civilian population That figure was reached on the basis of innumerable studies which had been made by various agencies including the United States Public Health Service, our own Bureau of Economics, the British figures, which had to do with Britain's method of securing physicians, the method of securing physicians in Sweden and Spain and so forth On the basis of all those figures the Procurement and Assignment Service itself established as a reasonable quota for this year 1 doctor to each 1,500 people and made the statement that when the enrolment had reached that figure physicians would not be further withdrawn from that state

Senator Pepper That statement wasn't kept then, was it? *Dr Fishbein* In some of those states there never was 1 doctor to each 1,500 people There are many areas of the country where that figure has never prevailed Naturally you could not have begun the war on the basis of saying "We will take no physicians from South Carolina"

Senator Pepper You don't mean to say, Doctor, that Dr Lahey and his staff didn't know that? *Dr Fishbein* They knew that, they knew that very well, but bear in mind that before—

Senator Pepper (interposing) Are you aware of the testimony that he gave that they had weighted these quotas, taking into consideration the disparities in the several states? *Dr Fishbein* Yes sir

Senator Pepper You don't mean to say that Dr Lahey wasn't capable of doing a competent job in the making of these quotas, in the setting of these quotas? *Dr Fishbein* I think the Procurement and Assignment Board has done a most competent and efficient job all the way through

Senator Pepper And you would regard Dr Lahey as competent to take into consideration these differentials and when he says that he made a weighted quota for South Carolina you would think that he knew what he was talking about? *Dr Fishbein* That is correct

Senator Pepper And when he later came in and said that South Carolina had contributed 170 per cent of that quota then the conclusion is inescapable, is it not, that in some way or another there was not a proper coordination in the protection of the health of the armed services and of the civilian population? *Dr Fishbein* We began the war with the highest percentage of physicians to population of any nation in the world, approximately 1 doctor to each 700 people We had a disproportionate distribution of those doctors, which is a fact that has been known at least since 1913, namely that it is the tendency of doctors to congregate in large cities A disproportionate distribution of doctors has always prevailed in this country to a considerable extent, but there I want to be fair and say also that there are other disproportions in this country which have not yet been settled

When you began to enroll doctors there seemed to be such a vast supply of doctors for an army in training of one million men—which was at first contemplated as every one knows—that no thought was given to the idea that we might strip any portion of the country

Then, after Pearl Harbor, when we moved up suddenly to a concept of an army of four and a half million men in the armed forces, your demand became tremendously greater on all types of professional service, including doctors Now, when you move up to seven and a half million there will be still more—

Senator Pepper (interposing) Yet it is a fact is it not, Doctor, that so far at least up until the present time, in the recruitment of doctors there has not been any overall authority which had weighed and measured the needs of the armed services and the needs of the civilian population and in the taking in of doctors taken into consideration the needs of both? *Dr Fishbein* The Procurement and Assignment Service has no authority to tell any doctor to go in or not to go in They merely have the power of declaring that he is or is not essential in the position which he occupies, making that recommendation to a local board, which has the real authority The authority rests with the local draft boards and there is no authority over men over 45 years of age at the present time and that constitutes well over half of your medical profession

Senator Pepper And there has been no central authority so far which has considered the overall health needs of the civilian population along with those of the armed services? *Dr Fishbein* That is not true because the Procurement and Assignment Service, when established by the President, was definitely charged with considering just that distribution

Senator Pepper Then it hasn't functioned in that capacity has it? *Dr Fishbein* I would say that it hasn't functioned 100 per cent I know very few agencies that have But I would say that it is functioning better all the time

Senator Pepper Yes, it may be functioning better but within the week Dr Lahey testified before this committee that up until the present time there has been no consultation by anybody that he knows of, on behalf of the civilian population, as to the retention outside of the armed services of the number of doctors necessary to maintain the health of the civilian population And you don't know, in your official position or with your wide knowledge, of any authority that has been permitted to speak authoritatively for the civilian population in preserving its quota of doctors, do you? *Dr Fishbein* Well, that is not quite correct either, for the simple reason that industry—

Senator Pepper (interposing) Who is responsible for 170 per cent of South Carolina's quota going into the service?

Dr Fishbein I would say largely the general system of Selective Service having complete authority over men under 45 years of age

Senator Pepper Are you represented on Selective Service?

Dr Fishbein No, sir

Senator Pepper Does anybody represent the civilian population, with respect to doctors, on the Selective Service Board?

Dr Fishbein No, sir

Senator Pepper Then what I suggest is true? *Dr Fishbein* To that extent you would be correct

Senator Pepper So that the Selective Service boards are the representatives of the armed services for the acquisition of men, not the representatives of the civilian population? *Dr Fishbein* That is correct

Senator Pepper Now Doctor, does this Assignment and Procurement Service have representatives in the counties? *Dr Fishbein* It doesn't quite go down that far I would say that many counties have representatives who are set up through their state agency, but they are just advisory There are many counties in this country that do not have a representative of the Procurement and Assignment Service in them, some do and some do not

Senator Pepper You said that our doctors were like lots of other people and had gravitated into certain large centers so that we had a disproportionate distribution of doctors over the country? *Dr Fishbein* Yes, sir

Senator Pepper Now public health is a question of fact, is it not? *Dr Fishbein* Yes, sir

Senator Pepper It is a question of geography the need for public health exists where the people exist? *Dr Fishbein* Well, the need for public health exists everywhere, whether there are people there or not

Senator Pepper We are not thinking about making the cactus more healthy, we are talking about people

Dr Fishbein My point would be that a swampy area in a district where there were very few people might still be the breeding place for enough mosquito menaces, so your biggest health problem would be in that area with very few people

Senator Pepper Let's augment my statement by saying that the problem of public health is related to the needs of the people of the country and to those conditions which endanger the health of the people? *Dr Fishbein* Correct

Senator Pepper Now then, we are engaged, it has been said, in a total war are we not, Doctor? *Dr Fishbein* Yes, sir

Senator Pepper Do you regard the health of the people as being essential to the effective prosecution of that war? *Dr Fishbein* That is vital to the effective prosecution of the war

Senator Pepper So we cannot, in your opinion, successfully wage this war unless we attend adequately to the health of the people? *Dr Fishbein* Correct

Senator Pepper Now, then, what plan has the American Medical Association been able to devise that would assure the public health of the people of the United States? *Dr Fishbein* That is the broadest question yet In the United States we have a vast public health system beginning with the United States Public Health Service and including also the public health departments of the states and counties, where there are such available, and through the contact of the Procurement and Assignment Service with a special committee on public health, arrangements have been made to declare essential—so that they would not be taken up by the Selective Service boards—all important public health officials

The Procurement and Assignment Service established a special committee on industrial medicine There was also established a committee on industrial medicine with the Health and Medical Committee, which was a part of the Office of Defense, Health and Welfare There is also an Industrial Medical Division in the United States Public Health Service There is also a Committee on Industrial Health in the American Medical Association No one man perhaps is a member of all four of these Some men are on various committees These various committees having to do with industrial health have given the most careful consideration to the problem of maintaining industrial physicians for all industries associated with the war effort They have passed on the industrial physicians whose names have been sent either to the Local Procurement and Assignment office or the national Procurement and Assignment Service as key men necessary to the health of the workers in industry

Many industries throughout the country have large industrial establishments many have small industrial establishments Great Britain has recognized the vital character of this problem by having a regulation that any industry employing more than 500 men should have a full time physician associated with that industry and when they employ more men they should have additional physicians and should have an industrial medical service We have not come to the point of regulation through any such federal agency, but we do have the general recommendation which has gone out from all of these committees on industrial medicine as to the manner in which industrial health should be maintained in this emergency

But we have been confronted with the fact—and when I say "we" I mean all persons seriously concerned with all of these

problems, because I have been concerned with them only as a man who gives public information as to what has gone on—we have been—

Senator Pepper (interposing) You don't mean that you work for the government? *Dr Fishbein* No, I edit a magazine, I am an editor

Senator Pepper For a group of professional men in the country? *Dr Fishbein* Yes, and I also do some writing for the public One of the problems which has confronted the medical profession most seriously is the fact that this is a young man's war on the combat front A doctor over 50 years of age falls to pieces under war conditions Great Britain has said that a doctor over 40 years of age falls to pieces under combat conditions and cannot be put up at the front

We have an armed force going out for this nation, an army, a navy and an air force The Air Force is a new body which has already demanded upward of 8,000 doctors to meet the needs of that body If we are to have an air force of 2,000,000 men they will need more doctors 8,000 will not cover their needs They must have young doctors If young doctors take positions in industry which can equally well be filled by doctors past middle age, the needs of the Army, the Navy and the Air Force if reduced to a minimum, cannot be met

Senator Pepper What do you regard as the essential needs of the armed forces, how many doctors per thousand men?

Dr Fishbein I say now that they are asking 65 men per thousand But if they reduce that to what Great Britain has, 45 per thousand, there would still not be enough young doctors to meet their needs if young doctors, men under 37 years of age take jobs in industry in order to avoid military service

Senator Pepper Are there any doctors in the armed services engaged in administrative work? *Dr Fishbein* By a joint directive from the Joint Army and Navy Board, both Army and Navy medical departments have been instructed to take from the desk every doctor capable of giving medical service in the field

Senator Pepper Well now, Doctor, suppose that you should find doctors occupying key places in industry, that is the maintenance of the health of the employees of companies that build ships and cannon and airplanes and the implements of war, then it would be the old question of determining which is more important the man or the gun wouldn't it? *Dr Fishbein* Senator Pepper that question has been given the most careful consideration by groups of the leading industrial physicians in the United States and I mean the industrial physicians for organizations as large as General Motors, du Pont Chrysler and Ford All these men who are the leading industrial physicians in the United States have sat on these boards, which are making the decisions as to what constitutes an essential physician in industry

Considering this matter purely as a matter of general information the kind of knowledge that any man can have, it is quite obvious that a man who has built up an industrial organization for a great industry of the scope of General Motors or du Pont, and who has all of his physicians of various grades and specialties rendering service, does not wish, in wartime, to see one man moved out of that job

We didn't like the idea of taking what I would say were seven key men from the headquarters of the American Medical Association because we have to take in other men, older, and train them to fit jobs for which we have trained men for ten and fifteen years But we made a decision very early that if the armed forces needed a man he was to go, and we would take an older man and train him in the job

Senator Pepper Now who knows more about the public health the armed forces or competent people who have the responsibility for the maintenance of our industrial operations, and the people who are in direct touch with the public health?

Dr Fishbein I would agree with you at once that the leading industrial physicians of the United States know much more about industrial medicine than I do and these decisions have been made by the leading physicians in industrial medicine in this country

Senator Pepper You mean the decisions in a local draft board? *Dr Fishbein* I mean the decisions having to do with the standards which should determine whether or not a physician in industrial medicine was or was not an essential man in that position

Senator Pepper Well now the man who is the head of a particular medical unit would also have some very important knowledge on that subject, would he not? *Dr Fishbein* The man who is the head of that unit this being a democracy, has open to him four or five different methods of approach for carrying his problem to the highest point, namely Washington He can carry his problem to the national Selective Service

System When a draft board takes a man whom he considers essential, he is privileged to file an appeal, he can carry that to his appeal board, he can carry it from the appeal board to the national Selective Service System. And specifically, if there are 11 doctors under 37 years of age employed in any hospital associated with an industry, and if a draft board takes any 1 of those 11 who are essential to that industry, the man in charge has two methods by which he can retain the man. The man can appeal and the industry can appeal on his behalf, that is through the draft board route. Now through the Procurement and Assignment route he can again appeal to the state procurement officer, from the state procurement officer he can appeal to the corps area procurement board, from the corps area procurement board to the national board of Procurement and Assignment, on which the final decision would rest. Now if no such appeal has come up on behalf of any man from the agency that wants to keep the man, the fault cannot rest with the agency at the top, it must rest with the man who failed to file the appeal.

Senator Pepper You mean that that is one of the methods he may pursue. Can you tell us how many men regarded as essential to the maintenance of health facilities have been kept out of the clutches of Selective Service by any of the Procurement and Assignment officials? *Dr Fishbein* Many hundreds.

Senator Pepper Give us your best estimate? *Dr Fishbein* I wouldn't like to give an estimate, but I will file a definite statement with you as soon as I investigate the matter.

Senator Pepper All right we will be glad to receive that. *Dr Fishbein* I would have to make a special investigation on that point, but I can have the information for you.

Senator Pepper Now in the various counties I believe you said there were representatives of the Procurement and Assignment Service? *Dr Fishbein* In some not in all. There are, for instance, eight counties in the United States with less than 5 people to a square mile. No one attempts to handle that situation by setting up an organization. In some two thousand counties there are probably men who would act for the Procurement and Assignment Service, or committees of men, in grading doctors as essential or as not essential.

Senator Pepper Dr Lamb has some questions.

Dr Lamb In connection with your point of a moment ago, Doctor, essential physicians in industry such as you were describing are not limited to those employed specifically by the large industries, that is to say, the health of industrial workers depends very largely on the average individual physician in a given community, or a member of a hospital staff, or what not? *Dr Fishbein* Yes, sir.

Dr Lamb Appeals on individual cases in other parts of the Selective Service, which I think this committee has already determined are not well protected by the present occupational deferment machinery, are no substitute for the good working of a system in which the overall plan is adequate—you would agree with that? *Dr Fishbein* That is absolutely right.

Dr Lamb So that your statement of a moment ago that these deferments might be secured for individuals is not in your estimation, any substitute for the adequacy of the plan?

Dr Fishbein Oh no. To move on to that next step which you have just raised I am convinced that there must be and will be—of course if this war lasts—an overall control over all professional and trained personnel. There must be, because in no field is there a sufficient number of men to meet the special needs created by an army of the size proposed.

Dr Lamb Right on that point we have at the present time about 40,000 physicians, you said, in the armed services? *Dr Fishbein* Yes.

Dr Lamb And I take it from what you said that they are the great majority of those under 40? *Dr Fishbein* Yes it is about half of those under 40. The average age of graduation is 28 years, and they graduate each year between 5,500 and 6,000 doctors. They take one year of internship before they are considered competent, and then if they care to go into a specialty they must take a residency. All that is being looked after, that is the maintenance of a minimum number of residents, and the maintenance of a minimum number of interns—that has all been given thought. In the twelve year period it would give you 72,000 doctors under 40 which is just about right.

Dr Lamb Now if we have a seven and a half million man army, as stated by Secretary Stimson as the goal for 1943, that would mean that if all those who are serving in the armed services are in that category of under 40 you will have all of the doctors of that age, is that correct? *Dr Fishbein* Fortunately for us they are not all under 40 and the exact figures are available as to just how many are now in the armed forces and in the civilian population, under 40 and above 40.

Dr Lamb Would you give them to the committee? *Dr Fishbein* I will leave them with you. For every five year age group beginning with the first year of the medical school and upward, as high as they go, we have all the doctors of this country classified—

Dr Lamb Dr Lahey testified that out of that 176,000 you would not classify more than 120,000 of them as effective physicians.

Dr Fishbein That is, effective for all purposes. Now we classify, for example, a bare 30 per cent of the men over 65 as effective for all purposes and when you get over 70 that would drop still further. Under 35 years of age 42,671 physicians from 35 to 44 41,558 physicians, from 45 years to 54 31,399 physicians. Now that gives you, let us say, under 45 about 84,000 doctors, effective doctors in the country, and they would be considered, let us say effective for all purposes, the men under 45 years of age.

Dr Lamb What part of those are included in the 40,000 or more in the armed forces? *Dr Fishbein* I would say that the large majority of them are included in the 40,000, but you see there is a total there of 85,000 doctors, so there is still half of those left.

Dr Lamb In other words we have approximately 45,000 doctors, or less, now available and considered to be in their prime, for the service of 120,000,000 people? *Dr Fishbein* Again that is not quite right for the simple reason that the age period from 45 to 55 gives you 32,000 doctors and from 55 to 65, 30,000 doctors. Now the effective age for the civilian population perhaps the best age for the civilian population of the doctor is 55 to 65.

Dr Lamb If I may interrupt, you have now given us 143,000 doctors under 65 and a moment ago we were discussing the possibility that only 120,000 physicians in the country were effective, and that gives us at least 23,000 who are not in the effective class. *Dr Fishbein* If you want to class all of the officers of the United States Public Health Service as not in the effective class—

Dr Lamb (interposing) We are concerned with their effectiveness for the purpose of caring for the civilian population and your figure of 1 to each 1,500 was based on that.

Dr Lamb (interposing) The testimony of Dr Lahey the other day indicated that he believed the figure in South Carolina was 1 to 4,100 before the war started.

Dr Fishbein In certain areas. He certainly couldn't possibly have said for South Carolina as a whole because that is not the fact and I am quite sure that Dr Lahey wished to bring out the facts. I will give you South Carolina as of—

Dr Lamb (interposing) Let us leave the question of South Carolina for a moment—

Dr Fishbein (interposing) I have it right here it is not too much trouble. I have my population tables here and it has to be calculated from that.

Dr Lamb Let's take the question of those areas within South Carolina and Texas and Oklahoma where the ratio is not 1 to 4,100 but there are some areas where it is 1 to 7,000, there are areas like that? *Dr Fishbein* Yes.

Dr Lamb That has not however stopped the Procurement and Assignment Board from taking doctors from those areas, nor has it stopped the recruiting teams from entering such areas? *Dr Fishbein* No that is not true the recruiting teams have already been withdrawn in forty-three states.

Dr Lamb I am not concerned with the fact that they have now been withdrawn, but with the fact that they have visited such areas and have recruited from them. How long ago were they withdrawn? *Dr Fishbein* Early in October.

Dr Lamb Commander Lapham testified that there were still perhaps four or five recruiting teams in certain states. *Dr Fishbein* Yes New York, Pennsylvania, Massachusetts, Illinois and California.

Dr Lamb To get back to the main point, you said that as of Pearl Harbor we began a much greater recruitment of doctors? *Dr Fishbein* Correct.

Dr Lamb We had at that time an army of about a million? *Dr Fishbein* Yes.

Dr Lamb Is there any reason why, at that time, it should not have been foreseen what the effect of taking 40,000 physicians from the communities into the armed services would be?

Dr Fishbein You are criticizing the government for not foreseeing many things that have not been foreseen?

Dr Lamb I am raising the question as to the operations of the Procurement and Assignment operations which, as I understand it, were based on previous plans worked out with the American Medical Association and carried out in the Procurement and Assignment by members of the American

Medical Association—*Dr Fishbein* (interposing) You are making about four assumptions which have no basis in fact.

Dr Lamb Thank you. Will you state your corrections?
Dr Fishbein You are assuming, in the first place, that the American Medical Association drew up plans for controlling the overall distribution of the medical profession in the United States, and they didn't.

Dr Lamb I am not assuming anything of the sort.
Dr Fishbein It is in your question, if you will have the record read.

Dr Lamb I am assuming that originally the plans worked out for Procurement and Assignment are those which were worked out through the operations of your county by county and state by state estimating system, is that correct?
Dr Fishbein They declared certain doctors available and certain doctors unavailable but—

Dr Lamb (interposing) And this is the framework under which Procurement and Assignment has gone on. What sort of protests has the American Medical Association made with respect to the continuation of enlistment of doctors?
Dr Fishbein There have been letters that have gone forward to the Surgeon General of the Army and to the Secretary of War. As rapidly as it appeared that in certain areas the condition was becoming what would ordinarily be called tight authorities representing the armed forces were informed of the fact that in certain areas of the country conditions were becoming tight and that some action should be taken. But that action had to be taken by federal agencies.

Dr Lamb But no effort was made to request that enlistments stop entirely and that some other system be substituted?
Dr Fishbein The withdrawal of the recruiting teams was not a matter of a single action suddenly withdrawing all the recruiting teams. Just as soon as it was apparent that recruitment should stop in certain areas, it stopped in those areas, even by direct recommendation from the corps area commander, who under our present system of Army control has the control, in his corps area over the recruiting teams.

Dr Lamb Would you testify, Doctor, that in January of this year it was impossible for the American Medical Association to foresee the effects of enlistment?
Dr Fishbein I think that they were clearly understood in January of this year by the Procurement and Assignment Service.

Dr Lamb Were there any representations by the American Medical Association to either the Surgeon General or the Procurement and Assignment Service, demanding that in January enlistments should be stopped of doctors and that some other system should be substituted therefor?
Dr Fishbein We are not in the habit of demanding anything.

Dr Lamb Were letters written along those lines?
Dr Fishbein Yes.

Dr Lamb Will you furnish the committee with any letters to that effect written by the American Medical Association in January of this year?
Dr Fishbein I think it would be more in order for you to request either the Secretary of War or the Surgeon General of the Army to produce such correspondence than to ask us to produce our correspondence with them, and I think that the Surgeon General would tell you that that matter has been looked after.

Dr Lamb Since this was a matter of initiative on your part it seems a correct request but the committee, I am sure, will be glad to request that correspondence from these other sources.
Dr Fishbein I am quite willing to ask the permission of the Secretary of War to send you the correspondence we had with him, if you wish to have it. I don't know where these authorities lie.

Dr Lamb I am sure that Senator Pepper would be glad to correspond with the Secretary of War to secure that correspondence. Now this question with respect to the ratio of 1 to 1,500 obviously that is an average and therefore has very little relationship to this 1 to 4,100 or 1 to 7,000, or whatnot?
Dr Fishbein On that I agree with you.

Dr Lamb Yet it is your belief that quotas should be established for areas in which those ratios prevail and that further recruitment of physicians should be carried on through the Procurement and Assignment Board?
Dr Fishbein On the contrary, I have stated to the Procurement and Assignment Service repeatedly, and indeed as late as yesterday, that a quota based on an overall quota for a state like Alabama, where they have one large city with a concentration of doctors in it, and a large rural area without a concentration of doctors, that the setting up of an arbitrary quota for the state of 1 to 1,500 would produce an inequitable and intolerable situation.

Dr Lamb You have so protested since last December repeatedly?
Dr Fishbein Yes, that is true.

Dr Lamb Have you letters written to that effect over this period of time, or were those protests oral?
Dr Fishbein I imagine I can find some written protests but the committee

could call, if they wished, various individual members of the Procurement and Assignment Service to whom I have stated definitely that the answer for Alabama as a whole, for Florida as a whole, and for any of these states where they have one or two large cities and a large rural area, the answer is not by a state quota.

Dr Lamb You stated earlier that of course no one would have wanted South Carolina to be told that she should not send physicians to the Army. Is there any reason an overall plan might not have excluded, let's take for example, the state of South Carolina?
Dr Fishbein The one reason for an overall plan that would be applied indiscriminately on a broad basis is the situation of permitting—and that still prevails—of permitting young men whom everybody knows ought to be in the Army to stay out of the Army. When you have an army that needs young men preferably for the kind of war that is being fought, when a considerable percentage of the army's needs supplied by physicians over 50 years of age, who perhaps should not be in at all but were needed to meet the army's needs, who therefore enlisted and who will be retained in this country in important posts in connection with training camps, when you got to a community as I did in Albuquerque New Mexico, in Artesia, New Mexico, and in Wichita Falls, Texas, and in certain areas in Illinois, where numbers of old physicians have gone, and young physicians, under the statement that they were essential to some industry or because they had one child or two children failed to enlist, you will observe that you destroy the morale of the group in that area.

I venture to say that is probably the chief difficulty of the doctors as a whole in the country at this time. Men under 37 are holding positions in industries, in industrial medical plants, and are holding those positions while much older men are going from those very communities to meet the needs of the armed forces.

Dr Garfield May I ask you a question, Doctor?
Dr Fishbein Yes.

Dr Garfield Why couldn't men over 40 take care of the base hospitals in a thousand or so army hospitals in this country? How many of the younger men are in active service? Are you aware of the fact that the Seventy-Third Evacuation Unit has 40 of the best young surgeons in the country. It was formed in February, and from February until now they have been stationed in some small hospital in California doing nothing?
Dr Fishbein I am essentially a civilian doctor and I venture to state that if you were to ask the United States Army Medical Department about the necessity for physicians in the armed forces and how it is proposed that they will use them, that the United States Army will be able to tell you why physicians must be in training.

I was asked on behalf of a physician from Boston who is a well known, competent ophthalmologist and who had enlisted in the Army, why that physician had been three months in a hospital and in a medical unit of the Army in Alabama without seeing any eye cases. But if the tank unit with which he had been associated was at that moment in Egypt he would be seeing more eye cases than he could possibly handle, and he must be trained with his unit. You can't train him in Boston to go with a tank unit when that unit starts out.

Dr Garfield Do they train him in eye work, Doctor?
Dr Fishbein They train him primarily in the functions of a medical officer in the Army. As far as I know—and again I am no authority on military medical service—it becomes essential in operating the armed forces to train men with the units which they are to accompany. You can't train a man in one place and then order him to the unit when the unit goes into battle.

Dr Garfield Isn't it true that there are forty base hospitals being built in this country, with unnumerable army hospitals throughout the country and couldn't doctors over 45 man those hospitals?
Dr Fishbein They not only could, but there are many, many doctors over 45 doing that. I have seen a urologist whom I know to be 57 years of age working in one of those hospitals. I have been in areas in Florida, in army areas within the past year where I have seen gynecologists operating on soldiers. Those gynecologists enlisted in the Army. They were men well over 45 years of age, and they were enlisted with the definite idea that they would be retained in this country.

But again if we must have young men with the Army, if we must have men under 37 years of age, or at least under 40 years of age, to meet modern condition of warfare, and if the needs of the Army in combat are to be met, some over all agency must be concerned with utilizing the supply of young men and replacing them, as far as possible in civilian life and in the whole area, with older men. That is scientific handling of the men.

This is as good a time as any to correct a complete misstatement of fact. The policy has been adopted by the Procurement and Assignment Service, by the War Manpower Commission and, after adoption by them, approved by the American Medical Association, for the setting up of prepayment plans in all industrial areas where the needs of a rapidly growing industrial community demand that as the most efficient way of rendering medical service.

Dr Lamb Doctor, when was that adopted? *Dr Fishbein* That was adopted by the Procurement and Assignment Service Board at least three months ago, it was adopted by the Committee on War Participation of the American Medical Association about two and a half months ago, it was adopted by the Board of Trustees of the American Medical Association in the second week in September.

Dr Lamb Has it yet reached the Procurement and Assignment local offices? *Dr Fishbein* It was given out to the public and was given out to all agencies, as far as I know.

Dr Lamb And they are already acting on that to the best of your knowledge?

Dr Fishbein To the best of my knowledge. Any one that wants to find it can have a copy of it. This is a large country and there are 120,000,000 civilians to be handled. In a service that embraces hundreds of thousands of people it is quite conceivable that some one man somewhere may not know everything that is going on. That is quite possible with respect to this man whoever the person is, I haven't any idea with whom Dr Garfield conferred on this matter.

Dr Garfield Three states, California, Oregon and Washington. *Dr Fishbein* If they will read the policy as it was adopted and has been published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and released to the press and in other ways given out, the plan for meeting the civilian needs in relationship to medicine has been thoroughly discussed and carefully worked out and is already functioning in many places. I will give you if you want—I will put them in the record—the names of many areas which are already being supplied with doctors because they have a shortage of doctors, and these are being supplied by a voluntary system, by doctors who have volunteered to move to other areas, and some of them are going to such places.

Mr Kaiser Then I take it, Doctor, you believe in prepaid medicine? *Dr Fishbein* I believe in prepaid medicine to such an extent that our own employees are insured under a hospitalization plan.

Mr Kaiser And you support it whole-heartedly? *Dr Fishbein* I don't say all plans. I believe in prepayment plans that are set up on a legitimate basis, there are many strange plans set up on a peculiar basis.

Mr Kaiser We are assuming that they are legitimate, we wouldn't want anything that was illegitimate. The next thing is, if you were in my position and you couldn't get your men into a hospital and you were in an area, what would you do about it? *Dr Fishbein* Well it all depends. This question was asked me by another committee before which I testified recently—

Mr Kaiser (interposing) This is a specific case, we have — men—*Dr Fishbein* (interposing) In the first place I believe always in operating within the law, whenever possible.

Mr Kaiser We are agreeable to that. *Dr Fishbein* States have laws regulating medical practice so that it is impossible to bring a man into the state of Florida—and I mention Florida merely because that is one of the states that has the most rigid laws that exist in the country—

Mr Kaiser (interposing) I would like to get back to where I was—you will get me lost. *Dr Fishbein* Washington, Oregon and California.

Mr Kaiser Yes. Here is the question exactly. I would like to get back to it because you are carrying me all over the country and I will be lost. What would you do about my specific case? *Dr Fishbein* If I were you I would ask my medical director to look into all the possibilities and not to try to solve the problem sitting where he is, but to go to the places where people have the information as to how the problem is to be solved.

Senator Pepper You mean to come to you, Doctor? *Dr Fishbein* No sir, come to the federal agencies which are charged with this task, and that is the Procurement and Assignment Service in this case.

Senator Pepper That are being run by the American Medical Association? *Dr Fishbein* Mr Pepper, I would question that statement very strongly. If you can establish the fact—

Senator Pepper (interposing) Haven't you worked hand in glove with McNutt on this problem, you consulted with him on his speeches, didn't you? *Dr Fishbein* No, that is

absolutely untrue. I have never seen—I can make this as a statement of fact, Senator Pepper—I have never seen in my life a speech of Mr McNutt before it was written. I have published two of them after they were written.

Dr Lamb Dr Fishbein, are you the chairman or director of information for Procurement and Assignment? *Dr Fishbein* I am Chairman of the Committee on Information. My purpose is to disseminate to the public—and this is the only function I have—through various press agencies and through medical periodicals the information which that agency wishes to send out.

Now, then, can you tell me any way in which the Procurement and Assignment Service could secure the cooperation and functioning of the medical profession without letting the doctors of the country know what their decisions were and how they function? Since obviously the publications which I edit, including medical and lay publications, are the best way of reaching the medical profession of the United States, the Procurement and Assignment Service would be operating inefficiently if it failed to utilize those legitimate means of publicity.

Dr Lamb And your services? *Dr Fishbein* Well, my services consist principally in this. When they send me a statement and say "Please give this publicity," I publish it in THE JOURNAL, I send it to all the other medical journals of the country, and I send it to the press of the country. Now if anything can be found wrong with that procedure, anything out of the way, which indicates any control over their actions, I would like to have you point it out.

Senator Pepper How often have you consulted with the Procurement and Assignment agency or Mr McNutt? *Dr Fishbein* When they had matters of publicity to be given out they sent them to me by mail in 95 per cent of the cases. I have been present at one or two meetings where they wished me to be present in order that I might give out publicity. I do not sit with the board at their meetings.

Senator Pepper Getting back to Mr Kaiser's question as to what you would do in his case in trying to provide medical attention—*Dr Fishbein* (interposing) I know that Mr Kaiser personally is not going out to hire doctors, he is going to ask one of his subordinates to handle the matter, that is obviously Dr Garfield. Now if Dr Garfield had utilized methods which other men in the state of Washington were utilizing to get doctors to replace the younger men, he probably could have gotten them.

Mr Kaiser I would like to make this point, and you will be glad to know this for your information, that in the Portland area we do have or did have that problem, but the doctors as a whole took hold of the problem themselves, organized all the hospitals and did render this service. We did nothing there, but that was not done in the other cities. Now what would you have where it was not done? *Dr Fishbein* What did Dr Garfield do? Did he go beyond those people to any agency? As far as I know he has not taken the matter up directly with the national Procurement and Assignment office. Obviously if he had they are in a position to look into the picture. But I do not believe, personally, that they would be warranted in marking his young men "essential."

Dr Garfield We organized our medical service at Richmond before there was a Procurement and Assignment Service in the first place, and we chose people who we thought were ineligible for the Army as much as possible. *Dr Fishbein* But the Army thought differently?

Dr Garfield No, I beg your pardon, the Army now is reclassifying them. *Dr Fishbein* I mean the Army might think differently because they thought differently on a lot of things. The standards for the Army have changed greatly since December 7. We didn't take in men, before December 7 who had less than twelve teeth, so we had a 35 per cent rejection on account of teeth. Now we have got a 3 per cent rejection on account of teeth.

Dr Garfield We took men from all over the country we got the best men we could. Now Procurement and Assignment says "You send all your men back to the Army and see if they want them," and that would break up our medical organization. There is one other thing. We had a shortage of beds in the area. Do you want us to go to the government and ask them for funds to build those hospitals? *Dr Fishbein* You have to ask them for materials, whether you ask them for funds or not.

Mr Kaiser No they don't give you the materials.

Dr Fishbein How do you get them?

Mr Kaiser Priorities.

Dr Fishbein Do you know what the priority rating on hospitals is?

Mr Kaiser It is A-1 when it comes to shipbuilding, because that is the only way you can get the doctors you are talking

about, over there, by giving them a ship to go over in I want you to get that clear

Dr Fishbein I happen to know what Dr Parran testified about concerning the building of hospitals. Now I know, and everybody knows, that in the new areas of industrial employment—

Mr Kaiser (interposing) You are getting away from my ship

Dr Fishbein No, I am not. In new industrial areas such as those with which you are concerned, because obviously you didn't have all those people there before we got into the war there are a total of about 5,000,000 people in the United States who have moved for an industrial job as the result of the war. Wherever they have gone we need hospitals, we need one at Valparaiso, Florida, we need them out in Richmond, probably and we need them in Vancouver—but it is impossible to build a hospital using private funds or government funds now without obtaining a release on essential materials.

Mr Kaiser We are doing it today, increasing our facilities.

Dr Fishbein I would say, Mr Kaiser, that you are a very strong man and you get many things done that other men who are not quite so active do not get done.

Mr Kaiser That is a beautiful out! But again how can we get the young man over to do the fighting unless he has something to sail in?

Dr Fishbein And how can you get him to sail unless you have a doctor with him?

Mr Kaiser He therefore needs transportation and his health and the health of the men that are building this transportation becomes fully as important as the men we send over.

Dr Fishbein Well that is slightly debatable whether or not a sailor or a marine who is fighting is more important than a shipbuilder but I don't want to debate that.

Mr Kaiser Please I asked you a question and don't give the answer from me. I ask you to give it for yourself. Is it important to have transportation? *Dr Fishbein* It is of the utmost importance.

Mr Kaiser And is it equally important to have the men there to build the transportation? *Dr Fishbein* It is important.

Mr Kaiser Is it equally important? *Dr Fishbein* Equally important?

Mr Kaiser Now the next question is. In that particular area where we didn't have that service, wouldn't you have created it? *Dr Fishbein* If I were there I would have had it.

Mr Kaiser I really think you would do a remarkable work if you would immediately get busy, where it isn't being done today and see that they are taken care of and rather than defending it, correct it. *Dr Fishbein* Pardon me, I am not defending anything. I am trying to show you that your statements have been made, and also those of Dr Garfield without a knowledge of what has already been done and is being done. You are concerned only with your little problem.

Mr Kaiser But it is only a model of them all, and I am now suggesting that you be concerned with them all and get this done. *Dr Fishbein* Suppose I told you that already we have reports from sixteen states in which there was said to be a shortage of doctors in certain areas that in ten of those states the shortages have been corrected. At Mobile Alabama, the shortage has been corrected by furnishing doctors to meet the shortage.

Somebody has to make the decisions as to whether or not a young man under 37 years of age, in industry, who is a physician, is more important to that industry or more important to the armed forces. That decision cannot be made by the man who employs that young doctor in the industry. That decision must be made by an agency which is able to look at the matter in a completely unbiased way.

Senator Pepper Would that agency be the armed services? *Dr Fishbein* No, by no means.

Senator Pepper Aren't they the ones now making it? *Dr Fishbein* No, sir. The President's directive to the Procurement and Assignment Service and to the Office of Defense, Health and Welfare which was Mr McNutt's office at the time because that was before there was a War Manpower Commission, the President's directive to them said that they should have the consideration of an overall distribution of doctors to meet the needs of the armed forces, of industry and of the civilian population. And simultaneously with that there went an order to the Army Medical Department, the Navy Medical Department the United States Public Health Service and all other agencies employing physicians telling them that this agency had been established by order of the President for that job, and that they would submit their requirements to the Procurement and Assignment Service, which would aid them in meeting their needs.

Senator Pepper You indicate, then, that the President intended that the Procurement and Assignment Service should act as the overall agency for the selection of medical personnel, but you don't mean to say that they have performed that function, do you? *Dr Fishbein* They have performed it within the law as it now stands, which puts the burden of ultimate decision regarding any man's service, when that man is under 45 on the local draft board.

Senator Pepper Well, then, the matter has not been decided by the Procurement and Assignment Service under the War Manpower Commission, it has been decided by the local service boards? *Dr Fishbein* The local draft boards. All matters of essentiality and the ultimate decision of forcing a young doctor into the Army have rested with the local draft boards.

Senator Pepper So the President's directive has not been carried out it has not been effective? *Dr Fishbein* It has been more effective in relationship to medicine than any similar effort in relationship to anything else.

Senator Pepper Well, in spite of that fact you have some states where more than 200 per cent of the quotas of the doctors have been taken in and in a state like South Carolina you have 170 per cent and in a state like Alabama 190 per cent who allowed that to happen? *Dr Fishbein* Well, it is still a free country—that is what permitted it to happen. The fact is that a man under 45 is under the control of the Selective Service board, a man over 45 is not under anybody's control in the United States.

Senator Pepper (interposing) They were allowed to volunteer, then? *Dr Fishbein* Yes.

Senator Pepper Was that decided by the Procurement and Assignment Service or by the armed forces accepting them? *Dr Fishbein* The armed forces obviously accepted them. But keep in mind your dates again! Keep in mind that the directive for the Procurement and Assignment Service did not begin until the end of October 1941.

Senator Pepper How many doctors had been taken in by that time? *Dr Fishbein* I will have to submit these individual figures to you they are all here on the tables, and I will answer all your questions when I get the record.

Senator Pepper Roughly how many had been taken in? *Dr Fishbein* Into the Army and Navy by October 1 1941?

Senator Pepper Yes. *Dr Fishbein* I would say roughly between 15,000 and 20,000, and 20,000 more came in between January 1942 and September 1942.

Senator Pepper So that the shortage that the civilian population now experiences is due to the number that have gone in since that time substantially? *Dr Fishbein* Very likely.

Senator Pepper And now the question is as to whether we are going to allow that hit and miss system to continue to operate or whether the President's directive is going to be made effective and some overall agency shall determine the needs of the Army and the needs of the civilian population? *Dr Fishbein* I would say that it operates effectively except for the unpredictable actions in certain areas of local draft boards. It operates effectively now, it didn't operate effectively before.

Senator Pepper You mean that it operates effectively only to the degree that the local draft boards and the armed services allow it to operate? *Dr Fishbein* The armed services are giving complete cooperation—

Senator Pepper (interposing) They are not giving complete cooperation if the draft boards which represent the Army are doing something that is not a part of a comprehensive plan for the whole country. *Dr Fishbein* I would say that to the extent—

Senator Pepper (interposing) The truth of the matter is that we haven't had a plan so far the President may have intended to set up one when he created the Procurement and Assignment Service, but up to a few days ago at least there hasn't been a national plan for the Procurement and Distribution of doctors to assure public health to the civilian population? *Dr Fishbein* I don't think such a statement could be made with all the facts before you.

Senator Pepper Where has it been operating then? *Dr Fishbein* Suppose we had done what we did in World War I—

Senator Pepper (interposing) I am not asking you to suppose. Where has there been an overall authority that has been looking at this picture as a whole? *Dr Fishbein* You mean an authority to pick up doctors and move them around?

Senator Pepper To say what doctors shall come in and what doctors shall stay out. *Dr Fishbein* The recommendation has been made in innumerable instances that certain doctors stay out, and the vast majority of Selective Service boards have respected those recommendations.

Senator Pepper But they were pure recommendations and didn't have any authority? *Dr Fishbein* Only recommendations.

Senator Pepper Now, Doctor, to get back to this group health insurance. You heard the testimony of Dr Garfield that the head of Procurement and Assignment in the state of Washington raised objection to their medical facilities being extended to the members of the families of their employees. Are you prepared to state from personal knowledge that that is not the fact? *Dr Fishbein* No, sir, I would like to look it up, though.

Senator Pepper All right, you have that privilege I am sure.

Dr Garfield Incidentally that is not only on the prepayment plan, but they wouldn't let us take care of them as private patients.

Dr Fishbein I would like to ask you who stopped you, Doctor, from taking care of anybody? Did you try to take care of civilians and have them stop you?

Dr Garfield We were afraid to because they said—

Dr Fishbein (interposing) Oh, now, Mr Kaiser wouldn't be afraid.

Dr Garfield They stated that if we were to do that they would declare our doctors nonessential, they were cooperative up to that point.

Dr Fishbein Did you read that part where they said they would declare your doctors nonessential? *Dr Garfield* No.

Dr Fishbein You haven't that in writing? *Dr Garfield* No.

Senator Pepper Doctor, let me ask you this. The man who is reputed to have made that statement was head of the Procurement and Assignment for the state of Washington? *Dr Garfield* Yes, sir.

Senator Pepper He had the power to make recommendations as to who was essential and who was nonessential as a doctor, did he not? *Dr Garfield* Yes, sir.

Senator Pepper And that was the only governmental agency there was to make such recommendations, was it not? *Dr Garfield* Yes, sir.

Senator Pepper And you assumed that if the doctors had violated the restraint that he had imposed, he would have had the power to have recommended that they be regarded as nonessential? *Dr Garfield* Yes, sir.

Senator Pepper And that that recommendation would have been observed by the War Manpower authorities and by the Army Recruiting Service, emanating from Washington? *Dr Garfield* Yes, sir.

Dr Fishbein I would say that no man has that authority, that he has never been given any such authority by any agency that I know anything about.

Senator Pepper You mean that the Procurement and Assignment representatives in the states do not recommend as to whether a man is essential or nonessential? *Dr Fishbein* They have no authority to say to any man. Unless you do this and so I will make you essential.

Senator Pepper Do they have the authority to recommend to the Selective Service authorities those who are essential and those who are not essential? *Dr Fishbein* They recommend—

Senator Pepper (interposing) They do have that authority? *Dr Fishbein* They recommend under an established policy of the national Procurement and Assignment Service.

Senator Pepper But they do have the power to go into a community and say "That man is nonessential" and "That man is essential" and to make that recommendation to the Selective Service authorities? *Dr Fishbein* They have that authority.

Senator Pepper Now if that official chose to give furtherance to a policy of the American Medical Association against the particular kind of group health, and if he was, in furtherance of that desire, to designate a certain doctor as being nonessential, in all probability you say that the local draft board would take that man into the service if he was within the eligible age limit? *Dr Fishbein* I will have to come back first to the statement that the American Medical Association has such a policy—they have no such policy.

Senator Pepper I am not asking you that. I ask you if that Procurement and Assignment official were to make that recommendation to the Selective Service authorities that a particular doctor was nonessential, would the Selective Service authorities not in all probability take that man into the service? *Dr Fishbein* That is correct.

Senator Pepper Do you think it is wholesome public policy for the government to have as its representative in the selection of medical personnel a man who is in a position at least to further private interests by what he does? *Dr Fishbein* Well that would involve, if a different policy was adopted, the destruction of the entire Selective Service system.

Senator Pepper Would it be the Selective Service system or the system of the American Medical Association that would be disrupted? *Dr Fishbein* The American Medical Association has no system in relationship to these matters.

Senator Pepper No. I am asking you would it not be appropriate for decisions of that character to be made by some official who has no personal or professional interest in the matter? *Dr Fishbein* The decision now rests with the Selective Service, which determines whether or not the man is or is not essential.

Senator Pepper But the Selective Service, as you have said, in the selection of medical personnel relies on the recommendations of the Procurement and Assignment Service? *Dr Fishbein* I would say that in many instances they consider that that is authoritative, reliable evidence.

Senator Pepper If they do—and you put into that place a representative of the American Medical Association—that man has the power, at least, by his action to further a personal and professional interest, does he not? *Dr Fishbein* I would say that wherever you put a dishonest man or one who does not deal justly, you have trouble.

Senator Pepper But, generally speaking you try to disassociate a public official's functioning with his personal interest, do you not, or from his personal interest? *Dr Fishbein* I venture to say that practically every representative physician, whether or not a member of the American Medical Association, who today is charged with the duty of declaring that some men are essential and others are not essential, is carrying that out in a more high minded and idealistic way than it possibly could be carried out by any other official.

Mr Kaiser Senator Pepper, I think that the Doctor would be glad to know this. This is a conversation between Dr Cutting and Dr Fletcher, who is chairman of the State Procurement and Assignment Board of the state of California, and I will read just a portion.

Dr Fletcher said that as for the program [speaking of our program] as a whole it was not his place or jurisdiction to question the ethical end of it although he was against corporation medicine of which this is a type [this is right along the lines of your thought]. He thought that the California physicians' service and medical profession themselves should take care of it. If this group (which is our group) went into the coverage of the new housing projects going on in Richmond he would be very much opposed to it.

Dr Fishbein He has a right to be opposed to it.

Mr Kaiser Now you maintain that he is not human and being opposed to it would therefore, even though he is not human, and being seriously opposed to it—we have frankly felt very much his attitude of opposition. I don't declare him dishonest, but he is not in favor of it and still he governs, through his recommendations, the men that we can or cannot have, and Dr Garfield feels that he is doing him a great harm.

Dr Fishbein I will say again, and say it as simply as possible, that an attempt has been made, as nearly as I can judge it, from observing what has been done an attempt has been made to administer this recommendation of who is or who is not essential in a certain area with strict regard for the functions that the physicians were carrying out. I could give you innumerable cases. It is without regard to any question of competition in practice, distribution of practice, among the people who remain, or any such matter.

But the policies of the Procurement and Assignment Service on a national scale have held that inasmuch as this is a war in which primarily the services of younger men are needed with troops in the field that young men under 37 years of age who take full time positions in industry in teaching, in research with medical organizations or in any other way, and because they are holding such a position avoid being called into active service with the troops that those young men must be subject to some higher agency than the industry itself. They have adopted a policy. When you could show that a young man—as is the case with Dr Garfield who is himself a young man—when you can show that a young man is your key man that is all very well. But when you have a doctor under 37 years of age and you hold him because he is a specialist in nose and throat diseases, or you hold him because he is a specialist in urology, or you hold him because he is a specialist in obstetrics and a part of your organization, then obviously this higher agency which is looking toward the fact that we must win this war as our prime effort, and that we have to have young men to win the war, simply has to decide on a different level.

Senator Pepper Mr Weber wants to ask a question on that point.

Mr Weber On that point what particular function do obstetricians serve in the armed services?

Dr Fishbein A very good point. The United States government has set up a system whereby the wives of all soldiers, privates, in the Army, if they become pregnant and if they are in the vicinity of a camp, may have their deliveries in the hospitals of the Army. I have seen the nurseries in at least a dozen army hospitals filled with infants. I happen to know that there are hundreds of obstetric cases scheduled during the next eight months at Fort Knox, there are 90 cases a month scheduled in Beaumont Hospital at El Paso, Texas—and that prevails all over the country.

Mr Kaiser Old men that are falling to pieces can do that, Doctor like you and I.

Dr Fishbein They are using old men for that.

Dr Lamb What portion of the obstetricians now serving with the armed forces are being used for obstetrical purposes?

Dr Fishbein I will have to check on that figure.

Dr Lamb Would you say it was as much as 25 per cent?

Dr Fishbein I think they are being assigned to that and the care of these children.

Dr Lamb To date would you say that 25 per cent of those now serving with the armed services were so employed?

Dr Fishbein I think that would be reasonable, but there is still an expectancy in obstetrics.

Dr Weber Do you know how many expectancies there are in the city of Washington?

Dr Fishbein I should imagine quite a few—I have some clippings here.

Dr Lamb Has the American Medical Association made any effort to determine the use being made of doctors in the armed services?

Dr Fishbein We know the use that is being made. The reports are obviously available to various agencies like the Procurement and Assignment Service. On an average two to three complaints a week come to my desk from doctors in the Army and Navy to the effect that their services were not being used to the best possible advantage. I have one or two right with me.

Dr Lamb You have investigated those? *Dr Fishbein* Every one has been investigated.

Dr Lamb And you are satisfied that they are not correct?

Dr Fishbein Where they have not been correct I not only have investigated them personally but I have sent information to the Surgeon Generals of the Army and Navy, giving them only the area, and wherever possible the man has been moved.

Dr Lamb How long has the Massachusetts General unit been serving in Florida? *Dr Fishbein* I couldn't tell you.

Dr Lamb Has it been there since January? *Dr Fishbein* I couldn't tell you where it is at all.

Dr Lamb Do you know what use is being made of the Massachusetts General unit at the present time? *Dr Fishbein* I can find out.

Dr Lamb I have information which leads me to believe that that, and a number of other units, are doing virtually nothing, that, for example, doctors who have been accustomed to operate as much as eight or ten times a day have not done that many operations since they entered the armed service.

Dr Fishbein I knew that question was coming. The only way I can answer it is to ask you this question. Suppose the General Staff or the Joint Army and Navy Board, or even some higher group, were to decide that it was time to start a so-called second front and that we were to mobilize a million and a half men for immediate shipment as rapidly as they could be shipped, as rapidly as Mr Kaiser could get the ships ready. Suppose they were to start to move them as fast as possible. And suppose that in order to get all these men ready for this movement we made effective, ordered into active duty, every hospital unit that had definitely been enrolled in the Army by that section, which is under Colonel Fitts. Suppose we got them all organized and ready to go and then suppose that the Grand Board of Strategy decided "Well, we can't go yet, this isn't the time," for some reason or other, "We may go next month or the month after." Then this army board is confronted with the proposition. Shall we order all these doctors back home in civilian life or shall we hold them one month or two months so that they can be ready?

Dr Lamb Or five or six months?

Dr Fishbein That is up to the Army. I will say again that I know nothing about military affairs and that I feel that in time of war the people at the top, including the Commander in Chief, must make those decisions.

Dr Lamb But these decisions are relative to the civilian population, and you have a definite interest in that matter?

Dr Fishbein I have the interest—

Dr Lamb (interposing) There are already 40,000 doctors in the armed forces. If we maintain the present ratio, and there is to be a seven and a half million army we will have

over 70,000 doctors in the armed forces, and if we have a 10,000,000 man army we shall have over 100,000 doctors in the armed forces. What would you say was the proper ratio of doctors to the population, which was the absolute minimum, and how much further can we go in that direction?

Dr Fishbein I have observed what has happened in Great Britain and I know what is happening in Russia, and I would say that since we have set up an agency which knows more about the total available doctors than anybody else, they have the assets and the needs, they know what the picture is, nobody else knows it as well as they do—

Dr Lamb (interposing) If I may interrupt you, may I say that that knowledge has not materially affected the question of these withdrawals on this scale because either enlistments or selective service, as you said, have previously had the prior authority. So that this agency with full knowledge, if it has such knowledge, has not been able to affect the outcome of these decisions?

Dr Fishbein I would say that it is within the authority of the Army to change its ratios any time they find it is necessary or desirable.

Dr Lamb Would you have any opinion with respect to desirable ratios?

Dr Fishbein I would not have the impudence to say that I would say to the Army "The situation in civilian life is becoming critical and will you, if it is at all possible, economize on your use of doctors, so as to leave the utmost possible for the civilian population."

Dr Lamb How recently have you said that to the Army?

Dr Fishbein I must have said that in personal conversations or in writing many times.

Dr Lamb What was the first date at which you said that?

Dr Fishbein Well, I think the first date at which I said it was in 1940 in June, when we had a joint meeting with representatives of the Army and Navy and the United States Public Health Service, at which time we pointed out that we had just so many doctors and that sooner or later we would have to have definite quotas for each group to be served, the armed forces and the civilian population.

Dr Lamb Why 'sooner or later', why not at the start?

Dr Fishbein Because at the start we had an excess of doctors in relation to the population of the country as a whole.

Dr Lamb Purely statistical?

Dr Fishbein I agree that there were certain areas that were without doctors, there always have been certain areas without doctors. But there are certain proposals that are being made in relationship to meeting these needs, which are so close to a totalitarian concept of government and so far from a democratic system of government that one opposes them on that basis.

Dr Lamb (interposing) In other words, Doctor, you feel that the proposals which are being made, some of them, are so extreme that it is preferable to go to the other extreme?

Dr Fishbein No, I have never said that. It is an old rule of mine in hearings never to permit the questioner to put words in my mouth so I prefer that you do not tell me what I propose. I will tell you what I propose.

Dr Lamb I am asking you to tell me what you propose.

Dr Fishbein I propose obviously, that the mechanisms which have been assigned by this government to meet this situation be utilized to the utmost.

Dr Lamb And revised? *Dr Fishbein* As needed.

Dr Lamb How would you revise them immediately? *Dr Fishbein* Already, wherever a shortage of physicians has been made clearly apparent—and we are conducting, incidentally, innumerable surveys, I have here the survey of the Public Health Service, of the Bureau of Economics, of the Procurement and Assignment Service, surveying all these areas—

Dr Lamb (interposing) But your decisions with respect to these surveys have been made on the previous assumption that the ratio of 1 to 1,500 for the United States as a whole can be applied in some fashion to these areas of shortage? *Dr Fishbein* I believe, if you had asked Dr Lahey that, he would have told you that that was certainly not the concept. Just yesterday the Committee on Allocations of the Procurement and Assignment Service determined that in any area where such a decision had to be made where there was a large city, and then a big rural area where you might get to 1 to 7,000, that obviously you would have to correct all your figures on that area on the basis that the large city was sucking in all the doctors and that special arrangements had to be made to meet those rural situations.

There is a physician in North Dakota who serves a rural area. He serves a radius of over 200 miles from his office. The only way he can serve that, obviously, is by motor car.

If you today took that away, he couldn't serve any of the area except what was right next to him. The only way he can serve that area by motor car is to travel as rapidly as he can possibly travel, and to have snow-tires in winter, and to have enough gasoline to permit him to move. Unless you grant that doctor extra snow-tires in addition to the five tires that he is allowed, and unless you grant him enough gasoline to cover his area, you decrease his capacity by 90 per cent.

Dr Lamb Yes, Doctor.

Dr Fishbein Now there are federal agencies which have already forbidden him to have snow-tires, they said "If you get two snow-tires you will have to give up two of your other tires."

Dr Lamb In that situation, wouldn't it be a good thing for the Procurement and Assignment Service to have some sort of responsibility for his getting those tires? *Dr Fishbein* I am not sure what service ought to have it, but the way I go about getting it is according to Mr Kaiser's technic. I see the Tire Administrator and say "We have no responsibility or authority, but we have publicity, and if you persist in what seems to us to be a rather odd attitude, we shall publish these facts."

Senator Pepper You mean you personally? *Dr Fishbein* I would send him a letter and I would say that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION feels—

Senator Pepper (interposing) I was interested in the initiative that you, as a private citizen, exhibited. You mean you, as the editor of THE JOURNAL, are going to take the responsibility for the enforcement—*Dr Fishbein* (interposing) No, only the publicity.

Senator Pepper But you want to be the whipping boy that will see to it—*Dr Fishbein* (interposing) I can write a letter to the New York Times, as many other people do, and get the publicity, they would print it, I wouldn't have to print it in THE JOURNAL.

Senator Pepper It is interesting that you, in your capacity as a paid representative of the American Medical Association, would exhibit the initiative that you—*Dr Fishbein* (interposing) I have always exhibited the utmost initiative of which I am capable in matters affecting the public health.

Senator Pepper I think the poor condition of public health in the United States probably proves you are correct in what you have said. *Dr Fishbein* Now the next step, Senator Pepper, concerns a doctor who is a pediatrician in a small town in Illinois. He draws his pediatric practice from an area in that neighborhood of a little over a hundred miles. The farm women bring in their babies to this pediatrician. As far as I know, no method has been provided for permitting farm women to bring their babies in to where the doctor is. In other words, they also must exceed their total ration of gasoline in order to bring the baby to the doctor.

Dr Weber Are pediatricians being taken into the Army? *Dr Fishbein* All classes of doctors are being taken into the Army.

Dr Weber I wanted to go back to the question of obstetricians. You mentioned that some of them are being used in their particular specialized professional capacity in dealing with the wives of privates around cantonments? *Dr Fishbein* Yes, sir.

Dr Weber And it has been the policy of the War Department, since the beginning of the Selective Service Act, to request that privates' wives not come to the camp areas. *Dr Fishbein* That is right.

Dr Weber They have provided some housing for officers' wives, but in the main we will say that 90 per cent of the wives of privates are remaining at home? *Dr Fishbein* That is correct.

Dr Weber So that the question of bringing children into the world, and their proper care in infancy, is a very critical question in American public health? *Dr Fishbein* And you are, of course, familiar with the actions taken by the Bureau of Maternity and Infant Welfare in relation to this obstetric service?

Dr Weber And yet we find that the Army is taking obstetricians and pediatricians into the Army in the same proportion and ration that they are all other doctors. *Dr Fishbein* Well, I know innumerable obstetricians and pediatricians who are in the Army. I would say that it is very likely—in fact, I have the evidence here of a number of areas where there is now a shortage of obstetric talent.

Dr Weber Washington, D C, I think, is one. *Dr Fishbein* In Germany they have a "fuehrer" for medicine in addition to Mr Hitler. This "fuehrer" for medicine has decreed—as it is quite conceivable we might sometime have in

this country—this fuehrer has decreed that a woman with a normal obstetric condition shall not have a physician, that the case shall be handled by some other group in the population, because the German army is so short of doctors. It is reported that, because of a very large number of wounded, they have had to withdraw from their medical group great numbers of doctors who were serving civilian populations.

Senator Pepper Doctor, let me interrupt you. In the United States do you have any statistics on the number of deliveries that occur in the several states in normal times in this country by midwives and not by doctors? *Dr Fishbein* Oh, yes.

Senator Pepper Take my state of Florida, for example. Are the majority of child deliveries in normal peacetimes by doctors or by midwives? *Dr Fishbein* That varies state by state, depending on the number of doctors available, the number of whites versus colored population. For instance—

Senator Pepper (interposing) Do you happen to know those figures for Florida? *Dr Fishbein* I think I can give it to you in the generalization, and I can get you the exact figures and—

Senator Pepper (interposing) Do you think the majority of deliveries are by midwives or by doctors in Florida? *Dr Fishbein* I would say that the state of Florida holds pretty well to the country as a whole, that the vast majority of deliveries of white women are by physicians, and in hospitals and that the majority of deliveries of Negroes are not in hospitals and not by doctors.

Senator Pepper If you will, will you put in the record information to show for the country, and state by state, how many deliveries are by midwives and how many by doctors? *Dr Fishbein* Yes, sir, and I can add the relative maternal and infant mortality which goes with that.

Senator Pepper For example, in Florida I was advised at one time that after the WPA had put on a lot of nurses and after the midwives had been given instructions in their duties that infant mortality in Florida in the next year decreased more than 10 per cent. *Dr Fishbein* I would believe that.

Senator Pepper And that was outside the medical profession. *Dr Fishbein* That is true, and that has been done in various other places—in Oklahoma, where four centers were set up for obstetric care, particularly for people in the low income groups, and arrangements were made to send good medical service from these four centers.

Mr Kaiser The Doctor has intimated that he would emulate my technic in getting results by threatening publicity. I think that brings home a very important question, because if he really believes in that policy, possibly the medical profession or medical society must likewise believe in it and that justifies the position that we have been holding. My feeling is that any one who, by threatened publicity, accomplishes anything both should be removed from the service of their country. I likewise feel that way both about myself and the medical association, if that is the policy they follow.

Dr Fishbein If we assume that the people of this country are the ones who run the country, the people must know. And the only way to get action is to let the people know. If you have an area in which there is a shortage of doctors and you want doctors, you have a right to let the people know that you are short of doctors. And then if you attempt various strong arm methods to accomplish things that are outside the law, and any newspaper finds that out, they have a right to let the public know.

Senator Pepper If the American Medical Association finds a deficiency in doctors in the country, are you going to give publicity to that deficiency and use the full glare of the spotlight of publicity to remedy that condition? *Dr Fishbein* We are doing that all the time.

Senator Pepper And if you should find that group insurance of a legitimate character would be a method of using more efficiently the medical talent and personnel of the country, are you going to use that same publicity to achieve that purpose? *Dr Fishbein* We not only have used the publicity but we have adopted the policy. There are thirteen state medical societies that have set up such plans there are over three hundred counties that have set up prepayment plans for supplying medical service. We probably have failed in our publicity in not letting enough people know that the medical profession is itself working out these plans.

Senator Pepper If you find instances in which members of the Procurement and Assignment staffs have used their public position and power to serve some private end, are you going to give the spotlight of publicity to that? *Dr Fishbein* I would be the first to recommend removal. If it came to my personal knowledge that any doctor endeavored to coerce Dr

Garfield by saying to him "You will either do this or you will be marked essential for military service," I would be the first to recommend that that man be removed from that position.

Senator Pepper: And if you found that there was an appreciable danger that that position was being abused to serve private ends then you would recommend the reexamination of the policy of using such personnel in a government position? *Dr. Fishbein:* If I found that any system was capable of coercion in what is presumed to be a democracy, I would recommend a change in the system, because I have always been a believer in democracy.

Senator Pepper: Do you regard the American Medical Association as a perfect example of democracy in its functions? *Dr. Fishbein:* I would say that it is organized like the United States government and it comes as near to functioning like a democracy as the government comes to functioning as a democracy.

Senator Pepper: Thank you very much, Doctor.

Dr. Fishbein: Now, Senator Pepper, does this conclude what I have to say? I have one more statement to make which has to do with a direct charge, using the language of gangsterism that the American Medical Association had put the finger on certain doctors to force them into the Army. That statement was made by a witness before this hearing and widely reported in the press of the United States.

In a statement—whether made here or in the press I do not know—that witness identified the man on whom the 'finger' was put. I would say that, typical of what we endeavor to do to get at the basic facts—that man himself has made a full explanation of what was meant by that statement, and it was entirely unwarranted.

I think it should be in the record that the statement that was made that the A. M. A. had 'put the finger' on some doctor to force him into the Army was a statement absolutely without any basis in fact and that if the doctor mentioned was questioned by the committee he would himself say that there had never been any one put any 'finger' on him, any one representing the American Medical Association.

Senator Pepper: In the case that you have in mind was a recommendation at one time made that he be classified as eligible for armed service? *Dr. Fishbein:* As far as I know—and from the man's own statement to me—he had some difficulty. He is a single man, he is without any family, he is not occupying what is generally considered a teaching position, he is doing some research in addition to his practice. He was having great trouble making up his mind whether he should enlist remain on the job in which he was or look for something else to do.

A man who was associated with him on his hospital staff and who was formerly—that is nine years ago—a President of the American Medical Association said to him 'If I were you I would join the Army.' That is the extent to which the 'finger' was put on the individual.

Senator Pepper: There was never any recommendation or classification by the Procurement and Assignment Service that he was eligible for military duty? *Dr. Fishbein:* Not as far as I know.

Senator Pepper: And there was never any change in that position by a reexamination of the matter? *Dr. Fishbein:* The man is serving in a hospital doing some research. I venture to say that if it was left to the Procurement and Assignment Service wholly they would probably mark him essential. He told me he was having trouble making up his own mind.

Senator Pepper: I am not talking about that. I am asking you whether or not the Procurement and Assignment Service ever classified him as eligible for armed service? *Dr. Fishbein:* I would have to look into that. He stated "no." I asked him that question, if the Procurement and Assignment Service had forced him in, and he said no.

Senator Pepper: I asked you whether he had ever been classified by the Procurement and Assignment Service as eligible? *Dr. Fishbein:* I don't know.

Senator Pepper: So the Army would not have gone out and gotten a club to put him in the Army, I mean the Procurement and Assignment Service if they were to "put the finger on him," would do nothing more than put him in the category of being eligible to be drawn into service? *Dr. Fishbein:* We must distinguish between the American Medical Association and the Procurement and Assignment Service. The testimony was that the American Medical Association had "put the finger" on him. The American Medical Association has not "put the finger" on him.

Dr. Garfield: Do you think we could get men over 40 to go to Vancouver and take the place of our doctors up there, well trained men? *Dr. Fishbein:* There is a doctor in Seattle who is about 42 years old, and he decided that his primary duty lay with the Army. He conducts one of the largest pediatric services in the United States in Seattle, and takes care of very important families and his income is up in the five figure brackets. He decided that his primary duty was with the Army. He inserted various advertisements stating that he wanted other doctors to come and take his place, doctors who were not eligible for military service because of age or physical status, and he got fifteen replies to his letter from doctors who wanted to come out and take that particular position.

Dr. Garfield: We are trying to get them. Were those doctors who wanted to come out there licensed in Washington? *Dr. Fishbein:* The doctors stated they were willing to take an examination.

Senator Pepper: Thank you very much, Doctor.

AFTERNOON SESSION

STATEMENT OF DR. E. J. O'BRIEN

Senator Pepper: Will you give your full name to the reporter, and your address? *Dr. O'Brien:* Dr. E. J. O'Brien, Detroit, Michigan.

Senator Pepper: And any representative capacity you have? *Dr. O'Brien:* I am a counselor of the American Thoracic Society and president of the State Medical Commission of Michigan, and I am chief surgeon of about eight of the hospitals in that city and some in Ohio.

Senator Pepper: Doctor, suppose you first make any statement that you have in mind, and then we can interrogate you if it will help you to bring out any of the matters that we are interested in. *Dr. O'Brien:* Senator, I was just asked to come yesterday afternoon, and I just flew down. However, I gathered quite a little bit during the course of the morning, and there are some things that struck me as very pertinent.

I think that the matter of public health as a whole is a great deal bigger than any individual, or any group of individuals, or any society. I believe that public health is something in which we are all vitally interested for self preservation, if for nothing else. I think it was brought out quite clearly this morning that there is some dislocation of proper authority and proper selection of doctors for armed forces and having enough left to take care of our civilian population which, to me, is just as important as the armed forces.

Senator Pepper: Doctor, you do then regard the public health as vitally related to the effective prosecution of the war? *Dr. O'Brien:* Oh, very much.

Senator Pepper: And if the government neglects to concern itself about the public health, can it hope to achieve an efficient use of its manpower resources? *Dr. O'Brien:* I don't think so. Senator, I want to state also I am a member of the American Medical Association, as most doctors are. On the other hand, I do not believe the agencies set up, either under or with the cooperation of the American Medical Society are efficiently working out. We know that lots of units—one was mentioned this morning, the Massachusetts General, and the Wisconsin Unit out at Battle Creek is doing nothing. The Northwestern Unit was there for months and months and months, the Harper Hospital unit of Detroit went out in July and it was in Custer for awhile and it is now in Sparta, Wisconsin, and at Camp McCoy, the Payne unit is scattered. They are sending part of that down to Springfield, Missouri, and the others are waiting to go.

Well, there is a serious shortage of doctors. And those are all our cream. When a unit goes like that, they take away the cream. They are big specialists in everything. It is not just haphazard, but they are the cream. And those men have been there for months, just rotting, really, because nothing is happening.

Take the hospital that I am chief of, the Herman Kieffer Hospital, there was one time there when we were down to two doctors. The Army did not take all of those directly, but indirectly. The young fellows that we naturally have that would come in to take the place of those that are leaving were in the Army so they were not available. A number of them were taken by the Army, and a number left in private practice.

I am not a believer in regimentation as such, but it seems to me that if you can take one doctor and put him into the Army

and send him wherever you want to, there should be some adjustment made where somebody could be kept where he is better.

Now, I think boards will, to a great extent—I am not talking about Michigan only, because they have been very fair—but they do not know the problems. I called a meeting of the Advisory Council of the Michigan State Health Department and the Sanitarium Commission, and I told them that we were being depleted very rapidly, and I was afraid of a break-down Michigan is supposed to have and has the best setup for the management of tuberculosis in this country. I do not think that anybody will question that. Still it looked to me as if it was going to be broken down. We had a committee appointed, of which I was a member, and we went to the Procurement and Assignment and told them that these individuals, herds of various sanitariums had to be kept there or the whole thing would break down. They agreed.

But there you, I think, is where there should be some central board or group that has teeth in what they do. It is hard to recommend—

Senator Pepper (interposing). Pardon me. For example, the Procurement and Assignment, if they were going to be the agency, would have the authority to say to the Army "Here are so many for you," and to the civilian population "Here are so many for you and for the various areas." *Dr O'Brien*. That is right. Somebody must have that authority. I don't care who has that but some one must have it.

I am particularly interested in the lack of what is being done, not only now but even before the war—in communicable diseases. The South, as you know, is absolutely disconnected in that there is nothing down there in the way of proper management of tuberculosis, and there are thousands of people throughout the country that are coughing and spitting tubercular bacilli all over the street cars and in your hotels and what not, and what is being done about it?

Certainly the American Medical Association is doing nothing. We in Detroit have done something about it. We got \$1,000,000 from the council just to go out and find them and we were just bringing them in, instead of the cases coming into the hospital. Seventy-five or 80 or 90 per cent—far advanced—we got them to 40 per cent of early diseased men that were picked up until one of our mayors, who is now serving a sentence for graft, cut our budget, because of economy so he said and dislocated things a little bit. But this should be a national thing.

And there is another thing. I heard Fishbein—I am not fighting with Fishbein and I am not fighting with American Medical—I want to go back to my original statement that medicine and public health are too big for individuals. And with regard to what I just said about tuberculars, we find them early and insulate them.

Here we have about ten million men anyway who are going to be screened and examined, and many of them are going to be found with tuberculosis and are being found with it, and some of them who do not have active tuberculosis but show healed childhood type that they must have gotten from somebody—everybody gets it from somebody who has it—but here are ten million examinations thrown into our lap, and what is done about it? A great deal could be done in controlling tuberculosis, and that is our home consumption again.

Health is essential to our military effort, and it is essential to civilian effort all the time. We are losing good men through that and we will continue to lose them, but we can get them if we go after them. That is our job, but is there anything that we have done about it? No. There should be some board or group.

Senator Pepper. Is tuberculosis considered to be increasing as an incident of the war, in certain areas? *Dr O'Brien*. It has not been tabulated as yet, Senator, but it will, unless what I am talking about is done. Take such cities as Detroit with no housing, people sleeping in trailers and crowded in all sorts of bad housing conditions which everybody is familiar with. And other work and insufficient heating and things of that sort—sure there is going to be a lot of it. But you can counteract all of that, Senator, with proper screening and case finding with beds enough.

We, in Michigan, have about three beds for every death and that is about what we should have in the country at least that much. That would mean that you would have to build about 90,000 more beds.

Well, that is not very much money these days is it?

And I say it means probably your health, Senator, because you do not know who is coughing in your face. But, if all of

those who are coughing tubercular bacilli around are hospitalized and got rid of it, you and your family would not be running the risk, and I would not, and my family would not.

But, it is very essential to have a plan, and I don't care whether it is the American Medical or anybody else—but I would like to see it done. I cannot see myself personally why we should have 1 man to a hundred in an army, perfectly normal and healthy individuals—I am not telling the Army what to do, because I know nothing about it—I was in the last war, but with 1 to a hundred in the Army and 1 to 1,500 or 1 to 2,500 or 4,000 people who have been thrown out of the Army because they are unfit, and all of their families and kids—well, it seems to me it is a little out of proportion. It seems to me we can have some boards with teeth that will correlate all of this.

Senator Pepper. Let me interrupt you to ask you this. According to your best judgment, how many people die every year in the United States from tuberculosis? *Dr O'Brien*. I think about 60,000 odd.

Senator Pepper. Sixty thousand odd. By adequate medical care and attention, how many of those deaths could be prevented? *Dr O'Brien*. Well, they can all be prevented. There is absolutely no excuse—I don't want to be too critical—one statement was made this morning that they stopped dying immediately of a certain thing. Well, but tuberculosis is a communicable disease and therefore a preventable disease. We cannot stop it right away, Senator, but if, for example everybody in the United States were theoretically examined tomorrow with an x-ray and you had beds enough to put in anybody who had tuberculosis you would almost stop the spread immediately. Many of them would be sick and die although we can salvage a big percentage of the tuberculars now with modern treatment but in the course of our lifetime, tuberculosis would cease to be a serious matter.

Senator Pepper. How many of the rejects from the Army have been attributed to tuberculosis? *Dr O'Brien*. I haven't those figures. I did not even know that I was coming, so I am unprepared with any statistics like that.

Senator Pepper. I know that in my state we got a few years ago, under the Public Works Administration program, the first and the only hospital for tubercular treatment of people in the whole state of Florida.

Since that time we have tried desperately to get an extension of the facilities of that institution and we utterly failed, on the statement that we did not have the facilities or the materials for it, and any extension there would have to be postponed until the end of the war. If it is being done in that state, then in no other part of the country is there any provision being made to take care of the discovered tuberculosis patients or victims who come in through the Selective Service System. *Dr O'Brien*. I might say in that connection, it has been one of my sore spots that there are all of these people suffering from it and nothing being done. We in Detroit, are alive to it and I tried to get some correlation between the Army's screening and the health department, but so far, we have not been able to get very far with it.

Senator Pepper. Dr Parran testified here before this committee that at least 25 per cent of the rejects from the military services under the Selective Service System could be rehabilitated with proper attention and care if proper facilities were provided. *Dr O'Brien*. I would probably add about 50 per cent more to that and make it 75 or 80 per cent or more that could be salvaged, because most of them that are found would not be there if they did not have fairly early lesions. That does not always follow but naturally you would expect most of them to have early disease and we most assuredly can salvage most of those.

Certainly 25 per cent is much too low an estimate. It is, according to our figures in the state of Michigan, where we really try to take care of tuberculosis.

But to take proper care of it you have to have some teeth in it and you have to have your beds to take care of them, and money to take care of their families.

Senator Pepper. Can you imagine Dr Parran stating, or imagine the condition which he was forced to describe when he said that he had recommended two hundred and ninety hospitals to take care of the millions of war workers that were being moved around from place to place? That was some good while ago. The President had approved two hundred and eighteen, but only two have been completed, fifty-one were

under construction, and he spoke rather discouragingly about any substantial improvement in the hospital construction program. *Dr O'Brien* Well, it looks to me like any breakdown in the health program for those who are left here to carry on the war and to build the ships and work in the munition plants and build the tanks and airplanes and so forth, if we think they are that important, and I guess they are—then I think the health of their families should be quite important too, and I do not think it is fair to just say "Well, that is the civilian population, and they will take what is left after the Army gets theirs."

I cannot quite visualize that. *Dr Lamb*, I believe, this morning carried it to that extreme. If we get up to ten million men—I think he figured there were 20,000 left for 160 million people. That does not make sense to me.

Senator Pepper One hundred and twenty million people. *Dr O'Brien* Yes. There has got to be some more correlation than exists at the present time, in my opinion, and there had to be some overall board that has teeth in their decisions.

Senator Pepper Doctor, you are a member of the American Medical Association? *Dr O'Brien* Yes, sir.

Senator Pepper You have been engaged in the practice of medicine for how long? *Dr O'Brien* I have been engaged in the practice of medicine for thirty-three years.

Senator Pepper And you are at the present time in a public capacity in the city of Detroit? *Dr O'Brien* That's right.

Senator Pepper Don't you think it is in the public interest that we approach this whole question of the health of the people with as much freshness of point of view as we can and with as little opportunity for prejudice, or personal interest to interfere with an adequate health program, as can possibly be done? *Dr O'Brien* Yes, sir. Health is bigger than individuals. That is my main premise—that health is bigger than that. That is all that we have got, and we have got to adjust ourselves to that. Whether you continue it in a democratic way or in a totalitarian way, it does not make any difference, if you can do it.

If of instance, I as a member of the American Medical Association, and the rest of my colleagues can do it as a medical association, all right, that is well and good, but I don't care who does it as long as it is done. But, there should not be any drop in that attempt to control disease because of personal prejudice or because of individual preferences or societies or anything else.

The American Medical Society has really got to be in charge in this way—I mean, they are the American Medical Association, and there are not any doctors of much consequence who do not belong to it. So that anybody who would be in control of a thing of that sort would have to be a member of the American Medical Association.

Senator Pepper Mr Weber had some questions.

Mr Weber This may be off the records, but I am just particularly interested at the moment in obstetricians because of a certain family problem. I am particularly puzzled by the fact that the Army makes no special rule in regard to obstetricians, that is, they take the men just as they take in any other group of doctors or dentists or whatever they are working with. What is your particular viewpoint on that? Do you think that obstetricians should be classified as essential to the maintenance of the civilian population or should they be taken just as ordinary practitioners? *Dr O'Brien* I have not really checked into it, but I heard this morning, and I did not know that there was such a large clinic following the Army around, I did not know that. I am not questioning the statement, but it is just something I had not known. Because of my ignorance, I would have thought that probably they were more essential at home. That goes for a few others, too.

But, I have an incomplete knowledge of that. In the last war, we did not have any.

Mr Weber Are you familiar with the Procurement and Assignment Service in the Detroit area? *Dr O'Brien* I am familiar with the men in charge, and I made that statement that they were very fair. When I went to them with the problem of the scuttling of our tuberculosis hospitals and told them who I thought was essential, and so forth, they immediately classed them as essential.

But can I just elaborate on that a little bit?

Mr Weber Yes, please do.

Dr O'Brien They are classed as essential and put off for six months. But what is going to happen in six months? We don't know. That is what I would like to know, I would like to have some board that controlled that that could tell us

Procurement and Assignment do not know what they are going to be told. Selective Service don't know what they are going to be told themselves, so we don't know where we are going to be.

Right now, those men that we thought were essential are now being held there, but how long they will be there, I don't know. That is an unhealthy thing to do.

Mr Weber I wanted to ask if the officials of Procurement and Assignment in the Detroit area are officials of the American Medical Association unit there? *Dr O'Brien* I would think so.

Mr Weber Do you know of your own personal knowledge? *Dr O'Brien* I could not say whether they were officials or not, but they were all members.

Mr Weber Your hospital there was cut down from sixteen physicians to two, did you say? *Dr O'Brien* We were down to two at one time, that is right.

Mr Weber And that was for a hospital of 900 patients? *Dr O'Brien* A hospital of about 700.

Mr Weber And it now has how many physicians? *Dr O'Brien* It had sixteen. I believe at the last count we had five.

Mr Weber How did it decrease from sixteen to two? What was the cause? *Dr O'Brien* That was a chain of circumstances. The Army took some, some left and went out into private practice—a thing that I do not think should take place in these times. I think, if you are essential and in a hospital of that sort, you should stay there until the service is over. Then the group of men who were supposed to come in—the residents that we draw from, were taken into the Army, so there wasn't anybody to get from that source.

Then there is another thing. I also think that there should be a little more regulation of the state boards of registration.

For instance, we have turned down a number of people lately that were in from Canada—highly qualified men, but we cannot take them. I am not for letting the bars down and taking in all the refugees and so forth, but I think there is a certain group that could be brought in, a lot of men in this country from South America—our good neighbors down there, that could come in and get a license, I would think, for the duration.

I am not for letting all men come in and take the place of the boys of our own country that have gone to war and have the boys come back, and when they come back find that their practice has gone and somebody else has stayed at home and is reaping the gravy.

I am not for that and I don't think that would take place if they were given a license just for the duration.

Senator Pepper If they were given a conditional license or a terminable license by the local boards? *Dr O'Brien* Yes, we cannot just let them come in and grab off the stuff.

Senator Pepper All of us are sympathetic with that. If it should be necessary for the federal government to step into this field on account of the concern about the national health, and if some local associations or local registration authority would not cooperate, you believe the national need would justify the federal government in using the power necessary to accomplish that end? *Dr O'Brien* I certainly do think so. I think that anything that is necessary should be done to the ultimate goal of preserving the public health and the control of it. And if those of us that are going along now cannot do it, let us get somebody that can. Let us not let people die needlessly when they can be salvaged, whether you call it totalitarianism or industrial medicine or group medicine or American Medical Association—I don't care. I want the health taken care of.

Senator Pepper Doctor, we thank you. There are hundreds of questions we should like to ask you, but we are running against time, and we appreciate very much your coming here. You have been very helpful.

I want to read into the record a dispatch from Dr Paul de Kruf, dated at Holland, Michigan, November 5, and is as follows:

Dispatches from the Washington Bureau of the Chicago Sun and from the United Press allege that in testifying before your committee November 3 I said that (quote) I had been expelled from the American Medical Association for liberal ideas (unquote). As you know I made no such statement. My testimony could not have been so grossly misunderstood and the falsification of my testimony must have arisen from sources attempting assassination of my character. I believe the vast majority of the physicians of America are sound at heart and are working for the help of the country. I have not attacked the American Medical Association as such. I believe that just as American labor is misrepresented by

certain racketeers so also American medicine is misrepresented by a few men who have tried and are trying to block cooperation between the American Medical Association and the federal government in organizing a health program that would strengthen the nation in the present emergency. I believe that the physicians of the country once they realize this will take care of the situation and clean their own house. Respectfully request that you read this telegram into the records Friday morning November 6

PAUL DE KRUIF

Senator Pepper I would also like to read into the record a telegram received from Dr Olin West, Secretary of the American Medical Association, dated Chicago, November 5, as follows

In an item in the Chicago Sun for November 4 it is stated that Paul de Kruif stated at a meeting of the manpower investigation subcommittee of the Senate Committee on Education and Labor that he had been expelled from the American Medical Association. Please be informed that Paul de Kruif has never been eligible for membership in the American Medical Association for the very simple reason that he does not hold the degree of Doctor of Medicine and in so far as our records indicate has never been licensed to practice medicine. Available information is to the effect that de Kruif holds the degree of Doctor of Philosophy. He has never been enrolled as a member of the American Medical Association nor as an associate fellow. In the item which appeared in the Chicago Sun it is stated that de Kruif attacked the American Medical Association for (quote) allegedly carrying on a recruiting campaign to put doctors into the armed services citing instances in which he claimed the organization had put the finger on doctors of importance in order to force them into the Army (unquote). Any such statement from whatever source it may emanate is without even the slightest foundation in fact. The American Medical Association has nothing whatever to do with the issuance of commissions or with the assignment of medical officers. The Association has earnestly attempted to cooperate to the fullest with all federal agencies concerned with medical and public health aspects of the war program.

OLIN WEST Secretary American Medical Association

Senator Pepper Also I will insert into the record a telegram from Dr Herman N Bundesen, president of the Board of Health of the City of Chicago, as follows

Re your telephone message requesting that I be in Washington on Friday morning I regret to advise that as chief of emergency service of the Chicago metropolitan area I already had planned an inspection tour of the district on Friday and Saturday which will take me out of Chicago and make it impossible for me to attend your meeting on Friday. I shall however hold myself in readiness for future orders. Much favorable constructive publicity is being disseminated over the country as a result of Senator Pepper's activities. Please give him my kind personal regards.

HERMAN N BUNDESEN M.D. President Board of Health

STATEMENT OF DR MICHAEL M DAVIS

Dr Davis My name is Michael M Davis, my address 1790 Broadway, New York City.

Senator Pepper Will you go right ahead, Doctor, and make any statement you care to make on this question?

Dr Davis I should like to make a statement that refers to three points. I should like to say something regarding the Procurement and Assignment Service with reference to the way it has exercised the responsibilities which the order creating it gave to it.

I should like to offer certain suggestions regarding the organization under which it seems to me the situation in the future should be handled, and, thirdly, I should like to say something regarding the manner in which physicians could in the future be assigned after they have been procured, to civilian areas which need them, a matter which this morning was hardly touched upon.

As regards the Procurement and Assignment Service, there are certain points which I feel should be called to the attention of the committee if they are not already in the record.

There has been discussion as to the quotas. That has been referred to a number of times and the fact that certain states have been overdrawn far beyond their quotas, while other few populous states are under their quotas. It may not be clear that the Procurement and Assignment Service, having been given responsibility for considering civilian as well as military and industrial needs, did not give out the quotas to the states until long after Pearl Harbor, until approximately the late spring—the late May or June—gave out to the individual states the quotas by which they were supposed in the future to be guided in the recruitment of physicians or in their advisory relations to Selective Service. The lateness of the date at which the quotas were given out are in themselves an evidence of the slowness with which the Procurement and Assignment Service moved from the stage of being a registration agency to a point at which it became an agency exercising effective influence on the actual task of procurement and assignment. Then it was not until

your committee brought out in your record the manner in which the processes of recruitment for the Army had actually proceeded—that is, not until the last few days—that it had become available to the public how unevenly the recruitment practices had been handled. There has been ample opportunity, both through THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and the general press, for both the medical profession and the public to be informed as to how recruitment was proceeding, so that even if the Army is slow to change its procedures, even if there were pressures of public opinion to stop medical recruitment in states which were getting up beyond their quota perhaps some change would be brought about so that the efforts to recruit physicians for the Army should be concentrated in this limited number of states which had and still have considerable numbers of eligible physicians within their quotas.

Senator Pepper Are you Dr Michael M Davis? *Dr Davis* Yes.

Senator Pepper Are you a physician? *Dr Davis* I want to make this clear. Like Dr de Kruif, I am a doctor of philosophy. I have been in medical work as a hospital administrator and hospital consultant and in the study of medical economic questions for practically all of my working life, but I am not a physician and therefore I am not a member, of course, of the organized medical profession.

Senator Pepper You are like Dr Fishbein in that most of your professional life has been spent in administrative matters affecting the public health, rather than in the practice of the profession of a doctor. *Dr Davis* Obviously, not being an M.D., I could not practice the profession of a doctor. I have been concerned with administration work in hospitals and related matters, and I have been concerned with studying and writing on the subject in many parts of the country.

Senator Pepper Did I understand you to say that you did not consider that the country had had this matter of the disparity between the number of physicians that were being retained in the civilian service and those that were being taken into the Army, relatively, until some weeks ago when this committee, first through the testimony of a doctor from Texas and through some other information, made the matter public in its preliminary report? *Dr Davis* So far as I have been able to ascertain, there had been no publicity before that time given to the unevenness of the way in which these quotas had been handled.

Senator Pepper Did you know that today, for example, there was being held in Washington a conference of the various representatives of the various agencies to discuss this very problem that this committee has disclosed to the country, and try to find some way to adjust the problem? *Dr Davis* I did not know that.

Senator Pepper Dr Lahey, the chairman of the Procurement and Assignment Service, made that announcement to the committee that he was calling such a conference. He also made it clear to the committee that such a conference had no authority, that there was still no over all, general agency created that had any teeth in it, as Dr O'Brien said, but it was just going to be consultation, because, as Dr Lahey put it, there was always a serious shortage of doctors for the civilian population. Is that your opinion that there is still a serious shortage in the civilian population of doctors? *Dr Davis* I am of the opinion that at the present time the number of doctors that has thus far been taken into the Army would not, taking the nation as a whole constitute a serious shortage if the doctors were more equitably distributed in relation to the need, and if the conditions of practice were such that the fullest opportunity could be taken to use the doctors' time to the maximum.

Senator Pepper At the present time, with the private compensation system that is in vogue is it likely that medical services are distributed according to medical need? *Dr Davis* I think we have very good evidence to the contrary because it has been perfectly clear that for many years past—it was suggested this morning—that physicians have intended to go in disproportionate numbers to the cities, that is, to the places in which the relatively large proportion of wealthy and paying patients were found. A very close correlation exists between the average per capita of wealth areas in the country and the distribution of hospitals and physicians. That situation has been going on for a long time and has been relatively, on the whole, increasing rather than decreasing.

Senator Pepper So that the existence of medical facilities and medical attention are more nearly to be found congruous

to the wealth and ability to pay for those services than with the need for those services? *Dr Davis* Yes, sir And I should like to point out another item which I think has a bearing on the unevenness of the Procurement and Assignment Service, namely, the vague and often confused character of the instructions which it has given out I am in very close touch with the hospital world professionally Recently at the annual convention of the American Hospital Association in St Louis a few weeks ago I had occasion to talk with hospital administrators from many parts of the country, men who have been very much concerned, of course with the maintenance of their staffs, and I was struck by the great difficulty which they had in agreeing among themselves on the basis on which they were to review their staffs and declare or recommend that so and so or so and so members of their staff, were essential or not I turn back to a pronouncement of the Procurement and Assignment Service, which I would like to read two or three sentences from This comes from the August 1 issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, where Dr Lahey, the chairman had set down a series of frequently asked questions with the answers as released by the board There are two questions that were asked relating to essentiality of a physician on the hospital staff

"On what basis do you call a man essential at a hospital? What yardstick do you use to call men essential to the hospital staff?"

And the answer quoted is "Each hospital is supposed to make its own list of essential men, which is submitted to the State Chairman of the Procurement and Assignment If he agrees they are considered essential If he does not, the hospital will be required to modify its list"

I submit that the hospital administration does not receive from that answer anything at all as to the standards on which they are to proceed in determining whether or not the individual staff member is essential And that is an extremely important matter, because such a determination involves the whole future of the staff member for a few years at least and it should be determined on what basis his essentiality is to be determined Clearly there should be some criteria or standards enunciated which should guide individuals in making up their decisions

This is merely one illustration which I offer of the failure to give clearcut criteria or standards on which individual physicians or hospital administrators or hospital boards should proceed to determine this very vital question

There is another point that I would like to lay stress on because it seems to me to be basic The whole foundation of the organization of the Procurement and Assignment Service has been built up, and the national organization has functioned on the policy that the primary responsibility rested with the states and localities and with a minimum responsibility on the national group I could illustrate that in this way It happened that last July a public forum on the air was held in which the then executive officer, Colonel Seeley of Procurement and Assignment, and myself and one other man took part At that time Colonel Seeley stated that the matter of meeting the civilian need for physicians in areas was primarily a local and state problem A month later than that in an official pronouncement of the Procurement and Assignment Service, published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the same principle was repeated, that the decision of civilian needs is essentially a state and local problem

So long as that principle carries through clearly, it is inconceivable that there can be a proper balance between the relative needs of states, so long as the state is the primary unit for decision That principle of course may be taken along with another point which goes to the root of the whole matter and has a great bearing on the future namely, so far as we have proceeded in relation to this matter of the judgment of the essentiality of physicians for industrial, military, or civilian service, the responsibility for the administration has rested wholly on a group of physicians It is perfectly clear, if one considers that in terms of the locality, that if you are considering the question as to whether or not additional physicians are needed in the area, that you place on a group of physicians living and practicing in that area a question in which their personal interests are inevitably involved with their public judgments And that is a decision which I think it is undesirable to place on any man I work with physicians, and I have worked with physicians all my life What I say is no reflection on them On the contrary, I may say that I have found and it is my opinion that physicians are especially idealistic and public spirited, with a high degree of public

consciousness of duty to the community, but I believe that it cannot be gainsaid that no men can be trusted with judgments affecting the lives of others when their personal interests and their public judgments are both involved in the same case

Senator Pepper Would that lead you to question the wisdom of the Procurement and Assignment Service in essentially having adopted the officials and the lists of the American Medical Association in the determination of who are eligible and who are ineligible for the armed services? *Dr Davis* I think that the very close working relations which undoubtedly exist between the Procurement and Assignment Service and the American Medical Association state and local branches are inevitable so long as the body set up by the federal government to deal with this medical manpower question is wholly a professional group

The point to which I am alluding is that I believe that the basic decision as to local and state needs should be made by a group in which certain public interests are represented along with certain professional groups And I believe that the overall situation nationally should be in a similar mixed body

Senator Pepper Is there not in your opinion a difference between taking the technical advice and counsel and deriving technical knowledge from technical men, and in putting the technical men in the places to make the final decision? For example, a judge on the bench will hear the testimony of medical men about a medical question but after all he sits representing the public and determines the decision according to the weight of the evidence and its competency and relevancy as he sees it While no one might question the absolute necessity of the Manpower Commission and the Selective Service in securing the advice and counsel of the medical men yet when it comes to the decision, if it were left to the medical men solely, that would make them substantially the administrative agency itself would it not? *Dr Davis* Yes sir, and I believe that until basic defect in the present whole setup is corrected we cannot have a satisfactory policy If I may enlarge on that point a little bit?

Senator Pepper Go right ahead *Dr Davis* It seems to me that if there is to be set up as your committee and others have suggested or that another congressional committee has suggested a general manpower body, as was suggested this morning by Mr Kaiser in which various interests should be represented as an authoritative body, that the same general principle needs to be applied in controlling the subsidiary but important question of medical manpower, that is that a body in which the groups of the public directly affected—labor, industrial management as applied to industrial areas, farm groups as applied to rural areas the general public and of course the medical profession and the allied profession of dentistry and others if you like—would be brought in to decide and outline the basic policies for the nation, and only such a body which incorporates in its decisions both the public points of view along with the professional and technical knowledge can be a proper body to leave these matters to

I would like to go further and apply that to the local level A situation such as Mr Kaiser described this morning indicates to my mind that the decision as to the local needs in his area for more physicians—for the introduction of more physicians—their employment in one fashion or another, and that in that decision the workers in Mr Kaiser's factories, and Mr Kaiser as the employer they both have a vital stake as well as the physicians of the locality have a vital stake in it and the basic decision on that or the recommendation as to whether more physicians are needed should be made by a group in which all of those interests are represented locally, as well as for the consideration of the technical information that the physicians alone have to offer

I would like to give an illustration of how the present policy has worked in a community very near to us here—that is, in Baltimore You have already heard and it is common knowledge, of the serious conditions in the suburbs of Baltimore near the Glenn Martin bomber plant In that Middle River section, it has been made well known through publications in the Baltimore papers and otherwise that there are over 50,000 persons now in an area that had a small population a while ago, and that there have been and still are only six resident doctors in the area To get a doctor out from Baltimore is difficult and expensive on account of the mileage charges, and so forth It may not be so fully known, although it is also a matter of public knowledge that, in order to begin to meet that situation a plan was worked out by the United States Public Health

Service and the United States Children's Bureau, acting under the authority which they have under the two titles of the Social Security Act, by which they can spend certain public funds appropriated to them by Congress at the request of the state health department. A plan was worked out to meet the very critical situation in obstetrical care in that area by which an additional physician, a woman physician, was to be there, a woman so that she would not be involved in the draft, and she was to be introduced on full time salary, and an arrangement was worked out with Johns Hopkins Hospital so that she would be given some special supplementary training for a period to make her ready. The plan was to place her in this area with a small trailer hospital, and it was to go into effect about the first of October. The plan in the initial stages was approved by the six local physicians, and I presume the county board of the county, because it was a county matter, not being within the city limits of the city of Baltimore.

Unfortunately, late in the game and after all of the arrangements had been made and after the woman physician had been engaged and was already about completing her training at Johns Hopkins, a change took place in the minds of the six local physicians and they changed their views and opposed the plan, so that the steps by which the United States Public Health Service and the Children's Bureau could supply their funds were broken down, because the consent of the county health officer and of the state health department necessary for the expenditure of those funds was no longer available, because the plan was no longer approved by the local medical group. In other words the needs of a number of women in this area with a population enormously grown from the original number and only with the same number of doctors that were there before, and yet the United States government could not proceed to carry out an already well made out plan because of the objection of the six local doctors in that area.

Senator Pepper The six private doctors, then, by objecting to that plan, caused the county health unit and the state health unit to disapprove of it, and that in turn caused the United States Public Health Service to be unable to go ahead effectively with the plan? *Dr Davis* Yes, sir.

Senator Pepper So that there was a case where a private group, because they privately disapproved of this health plan, throttled the public agencies which were trying to put public health facilities at the disposal of people who otherwise would not have them? *Dr Davis* Yes. The present system I believe, is basically wrong at the initial point where action should take place, namely, the decision as to the local needs being dependent on a group which inevitably has a double interest in view. In other words, it seems to me that any basic corrective requires the introduction of a joint body representing the public interests concerned, as well as the private professional group at both the local and national levels, in determining this matter.

If we come to the question, not of the procurement of doctors, but of the assignment of doctors to meet civilian needs, I should like to say something on that subject. We had this morning an example of one type of procedure which would be appropriate to an industrial area with greatly increased population, in which a single large industry was dominant. There it is possible to do what Mr Kaiser is attempting to do, namely, employ physicians on salary, utilizing existing hospitals, or building new ones, and set up a clinic with a staff of salaried doctors to carry on the care of illness caused by industry or caused by general reasons, for the workers and perhaps for their families. That scheme is one pattern under which doctors can be assigned, and it is nongovernmental in pattern in the local situation but it will require some authoritative governmental agencies or agency in there to engineer that pattern, because industry, by and large, and the organized workers in industry—and I mean large war industries in isolated areas—will have to have some help in most cases in order to get the doctors and get their plants organized as quickly as possible.

Senator Pepper Dr Davis, I had a questionnaire which came to me recently, and I did not have a chance to answer it until yesterday. It evidently was a uniform questionnaire that is being sent out from the medical officers or certain doctors in my state. Down at the bottom it said something about "The candidate for Congress will sign here." Evidently it was a questionnaire that was intended to be submitted to all candidates for Congress, and perhaps it was also intended to be addressed to all members of Congress sitting at the present time also. This questionnaire had a number of questions proposed, and one of them was "Do you favor the medical profession being sub-

ject to the antitrust laws as has been held by the courts?" And "Do you favor restricting the choice of the patient in the selection of the doctor?" and the like. One of the questions asked was "Are you willing to leave to the doctors of the country the provisions of facilities and plans and arrangements to meet public health needs?" In all of those other cases I was able to answer the questions in a way that apparently would be agreeable to the questioner, except in that respect, and I was forced to say "No not to the exclusion of the public agencies, the state and local government and the national government, and other agencies that have a direct relationship to the problem." Now do you believe that we can afford to leave to the lawyers entirely the question of what kind of laws we are going to have, and to the doctors entirely the question of what kind of medical and health facilities we are going to have, without the people having anything to say at all about it? *Dr Davis* I believe in something that I think Abraham Lincoln said, that no man is wise enough to tell another man what he must or must not do without that man's consent, and I don't think physicians are wise enough to decide public questions without public participation.

Senator Pepper It is a matter about which all of us should collaborate is it not? *Dr Davis* Yes sir.

Senator Pepper The national government, the state government, the local health agencies, the doctors and all the other agencies that are concerned about the vital question of public health. *Dr Davis* I should like to add something on the point that I was making a moment ago. It was mentioned this morning that the American Medical Association is in favor of and has approved the principle of prepayment plans. That is true. I have read about their approval, but that approval is conditioned in certain ways that are rather important. It is conditioned by the requirement that the plans must comply with certain broad principles which have been approved by the House of Delegates of the American Medical Association for prepayment plans, principles that were laid down some time ago, and actually since those principles were laid down the various local and state medical societies and the American Medical Association at least indirectly have been involved in action against a number of prepayment plans, so that unless the prepayment plans comply with certain requirements they actually are not approved by the American Medical Association, and the particular type of prepayment plan that, so far as I know, has not been approved in any instance by a state or local medical society is the type of prepayment plan which encourages a group of salaried physicians working as an organization, or staff of a hospital, or a clinic, and working and carrying on on the basis of group practice, with the support and voluntary contributions of the workers and their families if it be located in a strictly industrial area and organized to serve them. In other words, there are only certain types of prepayment plans that are acceptable to the American Medical Association and attempts have been made in many places, of which the situation in Washington in the District of Columbia was only one example, to prevent such plans. There is no indication that the American Medical Association or its state and local societies will accept the type of plan which, for instance, Mr Kaiser has suggested, because there is good evidence in my opinion, to show that in a time when the utmost possible must be done to make the maximum use of the doctors that we have got, and where you have a concentrated population you can get the most out of your doctors if you organize their time and not leave them to compete with another on the usual private practice basis.

I am not in favor of the federal system of medicine, but I think that during a war period, and with a limited number of physicians, I think the federal government is the only body that can exercise the necessary authority and exercise the necessary influence over the state and local bodies of all kinds to make the maximum use of the limited number of doctors that we have, even as compared with peace times, after we have furnished the Army even on a reduced ratio.

Senator Pepper In other words, during this emergency, such a so called group health plan, where its membership is based on voluntary cooperation, may be the only way that we can make the most efficient use of the medical services that we have? *Dr Davis* Yes, sir. And I also want to add that there are some local circumstances where such plans are not practicable. For example, in the state of California, the California Medical Society is practically the sponsor of the responsible body for the California Physicians Services, which sponsors a prepayment plan, but the prepayment plan is based

on the so-called "free choice" or private practice principle in which those in the area have a free choice. Such a plan is all right in peace times if the rates are low enough. It has not done very well in California so far, but there are circumstances in which such a plan may make out pretty well. There have been examples in peace times of such a plan working out very well in a place like, to mention one, Binghamton, New York, where a person may call on any physician in the community, and there it has worked out pretty well. On the other hand, you have another type of situation—you have rural areas where the number of doctors has been few to start with, and has been greatly cut down and where it is absolutely necessary to introduce a doctor in the community, like in Valparaiso, Florida. That was only accomplished after a council of the state medical society gave its approval, and only then was the state medical officer ready to send his formal statement to the Public Health Service, on the basis of which it was possible for the service to act.

Just a further word regarding the federal agency that must do this job. Assuming that there is some over-all national body which will include both public and professional representatives in determining policy, and assuming that the local need for doctors is also determined, not by a wholly medical group but by a similarly mixed group, I think it would be possible to expect an organization like the United States Public Health Service to be effective as the agent of the United States government for carrying through a program of assigning doctors and of organizing local facilities which will make those doctors time most effective.

Mr Weber: It does not have that authority at the present time? *Dr Davis:* It can only act now on the basis of requests coming from the state. It can only spend money then. I believe that in the period during which we are at war the President can declare any area an area of urgent need, and in those areas so declared, in health matters the Public Health Service would then have the right to send commissioned health officers into the area, irrespective of state license laws, to carry out any medical services in the area. Obviously, that is a power which would be exercised with caution. In that way they are aiding the local bodies. They could decide with the proper local people what hospitals should be built there if more are needed, and how the doctors' work should be correlated with the hospitals, and so forth.

If we just send doctors around or assign them, I should like very much to know just how these certain number of doctors which were referred to this morning as having very recently been assigned by the Procurement and Assignment, as to how they have been assigned and to what duties, and how they are supposed to work, because it is absolutely essential, as I brought out before, that their time shall be used to the utmost, and that is a problem of organization and not merely of ticketing certain doctors and saying to them "You go there and start practice." These men are mostly, in the nature of things, going to be men who have already acquired a practice. If they leave that practice, they are leaving everything they worked for, for the duration at least, and they may never be able to come back to it. Obviously, the government, which asks them to leave, directly or indirectly, must give them something, must pay their moving expenses, must give them a guaranty for the duration, unless they make an arrangement with industry, like Mr Kaiser told us about.

In other words, there is a problem required to meet our civilian needs. It requires organizing ability in which not only the doctors themselves are involved, but hospitals, industries, local groups in rural areas, the unions if it is a large industrial area in which unions are important, as most of them will be now. So that all of these bodies must be drawn in, and we must have a national agency which can furnish some personnel to help the localities to organize.

But, again, all these studies come after the basic decision as to what the needs are and what the general policies are and have been made by a group in which the public as well as the profession is represented from the start of the whole thing.

I have great confidence and I would like to be on record as making clear that I have great confidence in the United States Public Health Service. I believe that the United States Public Health Service, like every other group composed mainly, as it is, of medical officers, cannot easily work under the severe pressures to which it is subjected from the organized profession, local, state and national, unless it is protected against those pressures by being responsible to a mixed policy determination body in which public lay groups as well as medical

men are jointly members. Thus protected, I believe that the United States Public Health Service would be an effective body. Of course, I also believe that the organized medical profession has a proper and necessary relation to any such procedure as we are talking about, in an advisory way, but I believe that the experience of many types, and especially experience with the Procurement and Assignment shows that in making the basic decisions and as an administrative body carrying out decisions we cannot place reliance upon a wholly or primarily professional group.

I would like to say another word or two on the further question of assignment. There is a question of finances that is involved that may be rather important. How many million dollars is there going to be necessary for the federal government to spend to place into civilian areas doctors that will meet their needs assuming that there is some kind of an overall body that will determine the policy? I doubt if it is possible to make an estimate of that now that can be reliable because only after that has been canvassed in terms of the situation in each area, can that be determined.

We will have at least the following types of situations: first, areas to which the federal government must send a commissioned federal officer on salary and in uniform, who will carry on the care, preventive and curative, of the population in that area either alone, if he is the only man there, or in cooperation with the other doctors that may be there. That will be wholly a federal charge.

Mr Weber: And you think the number of such areas would be small? *Dr Davis:* Relatively so in comparison with the other types. There will be areas in which you have a large dominating industry, such as Kaiser for instance, in which the management of the industry and the workers would be able and desirous of meeting all of the operating expenses, and in which if hospital facilities were necessary, federal aid as is now possible technically under the Lanham Act would be available for building of the hospital if the material situation can be straightened out, but in which primarily the responsibility of the federal government would be to aid in the determination of the amount of need and the number of doctors, and in helping in an advisory way the unions and the management in organizing their scheme if they needed such aid and in furnishing them with lists of doctors, if they were necessary from a national pool, drawn primarily from the states that now have more doctors than their quotas provide for.

Another type is a mixed type in which a community needing more doctors but with diffused industries and with no outstanding or dominating ones and where it is possible that a number of doctors will go in there on a private basis to supplement the existing doctors but in which the federal government will have to meet certain expenses of moving the doctors and their families and of providing an initial guaranty and some funds so that they can set up their offices, and so forth, and possibly providing them with a certain guaranteed income while they are making their start in the new community.

I think it would be very difficult to judge as to just what the relative proportions of those different demands would be until we have made a statistical analysis of this situation. We have some of those, but immediate action need not wait until such further academic studies.

Dr Lamb: I think I would like to follow up this question of the Public Health Service. Is it not your impression that the Public Health Service has been by-passed in recruiting of doctors by the Army and the Navy? *Dr Davis:* I don't know quite what you mean by "by-passing" the Public Health Service. I think the general attitude of every one has necessarily been that the Army needs come first. Nobody wants to oppose the Army, or no individual wants to be in the position of saying that he doesn't want to go into the national military service.

Dr Lamb: I am sorry that I did not make the question clear. Why was the Procurement and Assignment set up separate and outside of the United States Public Health Service? Do you feel that the United States Public Health Service was competent to recruit personnel for the Army and the Navy? *Dr Davis:* I feel that it would have been far better for us nationally, and we should be very much further along today if the Public Health Service had been given the necessary authority, and of course some funds, a year ago—more than a year ago—when we first began to see this situation, and if a body representing both the public and the professions

as its advisory and policy determining group were organized so that the Procurement and Assignment Service would never have been called into existence in its present form, but in which a joint group of public and professionals would have been in a position to control the policy, with the Public Health Service as the administrative agency doing the actual job in the field

Dr Lamb You mean to say that if the United States Public Health Service had been designated originally to carry out the function of obtaining the medical personnel for the Army and the Navy, the public interest, that is, the medical interests of the civilian population, would doubtless have come to the fore much more quickly? *Dr Davis* Very much so, provided the Public Health Service, which is itself necessarily much subject to the same pressures from organized medicine that other medical groups are, had been protected against those pressures by the organization of this policy determining body composed of both medical and lay representatives

Dr Lamb In other words, if the job of recruiting had been placed in the hands of the United States Public Health Service, this advisory lay body would have immediately begun to exercise some influence on those policies? *Dr Davis* I think so, without question, because they would have been in a position to judge the facts from the point of view of the country as a whole

Dr Lamb Who first proposed the establishment of the Procurement and Assignment Service? *Dr Davis* I believe it is on record that the American Medical Association suggested the idea, and that that was taken up finally by the government and put through just a little over a year ago

Dr Lamb Your main point is that medical personnel, being a short item today, and one of which the supply can not be expended quickly, would face thoroughgoing change in the way in which medical services have been distributed? For example, in South Carolina—South Carolina has been mentioned very frequently here—there we have a state in which we have 1 doctor, let us say, to 6,000 persons. In New York we have 1 to 1,000, there is a possibility that some system of distributing medical personnel for the civilian population has to be worked out but there is not yet on paper any such method for distributing that personnel. That is what you have addressed to primarily?

Dr Davis Primarily, yes. And to point out that the body which must determine that method and those policies must be a group in which the public is represented by various groups as well as the medical profession

Mr Weber What you are saying is that the United States Public Health Service is the most competent to undertake the administration of any change in the distribution of medical personnel or services that may be necessary? *Dr Davis* Yes, sir, I believe that is so. I think if you were to set up a new body, you would practically have to duplicate not only the federal organization, but the local organization in the Public Health Service

Mr Weber Do you fear that the same interests that preferred to set up the Procurement and Assignment Service separate from the United States Public Health Service will likewise prefer that the United States Public Health Service not be the body to administer a new method of distributing medical personnel and facilities? *Dr Davis* No, not necessarily, and I would like to make myself clear on this point

In the first place I do not want to have it inferred that I regard the American Medical Association or the Procurement and Assignment Service as actuated by any sinister motives whatsoever. I have known physicians too long and I have known too many men in the American Medical Association Councils who are public spirited men of the highest type of individuals. I see no sinister motive. I see short sightedness and specialized points of view which do not take into account the other interests of the public that should be represented

As to the public health service, I think that I would not be able to say that you could get any other body any better than the United States Public Health Service. Certainly, we could not set up any other body at short notice that would be nearly as effective

I believe that the interests that are behind the—I feel that the Procurement and Assignment Service would be delighted to be able to use the United States Public Health Service as its field agent for carrying out the policies which it desires and that under the great pressure of public opinion, which I am quite sure is being created by the hearings of Senator

Pepper's committee which are now being conducted I am sure that there will be a great activation of methods on the part of the Procurement and Assignment if it continues to exist, but I think that the method which they would most prefer would be that the United States Health Service should be in terms of policy wholly subordinated to the Procurement and Assignment Service, that is that the policy determining body shall be the Procurement and Assignment Service, and the Public Health Service shall be an agent or a tool of that body in carrying out the policies

I also feel that such a scheme will not be very effective, for the simple reason that I do not believe that a group specialized as that has shown anything like the type of imagination or administrative experience which would be likely to make it effective

We have wasted a great deal of time already and time is very precious and action should be taken pretty soon

Mr Weber Coming back to your point—as I understand it, you said that the personnel of the United States Public Health Service and the Advisory lay personnel to that agency make it less amenable to the viewpoint of organized medicine than the Procurement and Assignment, is that right? *Dr Davis* Yes, sir

Mr Weber And for that reason, you feel that the United States Public Health Service will not obtain the support from the medical profession as a whole that you would give it, for instance? *Dr Davis* I am not sure about that. I am inclined to think that you can count on two things from the medical profession—you can count on their patriotism first. The individual position is relatively idealistic and certainly a patriotic man who, if he knows clearly what the nation wants, will do it. The trouble is he has not been informed about these matters by the chief source of information, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

If a major national body through this committee works out a policy and makes that clear to the whole people and to the profession I think you will have a very large amount of cooperation from the profession, which will spring even the American Medical Association largely into line if you set up an effective machinery in which the medical profession is represented, but not in control

Mr Weber You mean to say that the response of the medical profession and personnel in the country to national policy depends on the type of information that it obtains in regard to what the existing situation happens to be and you are saying that the organs of the medical profession at this time have not provided a genuine picture of what is happening? *Dr Davis* Yes, I think that is true. I think the medical profession shares with every intelligent man the conviction that they will be guided by the facts, if they have them, but they have not had them

I would like to put into the record something which will take me about a minute to read. It illustrates that there are local groups of doctors who are very keen on this subject because they are faced with local needs

Here is one illustration of what a local area could do with some government aid, as proposed in an editorial in the official journal of the Mississippi State Medical Society. It says

The doctor shortage in this country is growing more acute in our state and in the South each day. Practitioners must use all their energy in treating the sick instead of dividing their time with personal interests

The small town might have a medical center furnished by the town and the county consisting of a hospital and a medical arts building large enough to accommodate every doctor, dentist, pharmacist and the public health department. The hospital would function best if operated in the interest of all the people alike with the doctors treated on the same footing. Office building self supported from rent

such a setup a real center for treating the sick and educating the public. Center to be supplied with bus service for transporting sick to and from hospitals. (Mississippi Doctor 20 181 [Sept.] 1942)

If you sit down with a group of local doctors who have a local situation where the needs are pretty obvious once they are drawn to their attention, and with men who are really up against the local facts, you are going to be impressed by the fact that they are going to be like any other group of patriotic men who will work out the problem just as this editorial says, that here was a group of doctors who was trying to work out how the job could be done, and every doctor did the maximum for the local public which they are there to serve

I merely bring that out because you would get a very large amount of cooperation from the doctors all over the country as individuals and as groups, once the situation is clear to those doctors and the overall national policy is made a matter of patriotic duty

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

NAVY

TRAINING THE NAVAL PSYCHIATRIST

and

LIEUTENANT J J HEAD

Medical Corps United States Navy

At the National Naval Medical Center, Bethesda, Md., beginning early in the spring of 1942, certain courses were begun for civilian psychiatrists newly commissioned in the Naval Reserve. It might seem at first thought that such courses would be a waste of time, and the question might be asked "Why not put these psychiatrists to work in the Navy without delay? Why a teaching period for mature specialists in this field?" Experience thus far has shown the value of the present policy and the reasons which make such a training period necessary.

The transition of the civilian from peacetime habits of thought and behavior to a wartime military status is, in general, the greatest problem facing the nation today, greater, in the opinion of many, than the transition of the machines of industry from a peacetime to a wartime basis. The husky farm boy who is a good shot with a squirrel rifle is a good potential fighting man but not an actual useful unit until he has been trained in many new skills and ways of thinking.

The importance of the psychiatrist in the war effort is now well known. What is not so well known is the fact that a psychiatrist who is not familiar with the ruthless necessities of a military organization and its aims and requirements, namely "to keep as many men at as many guns as many days as possible," may create confusion and waste more time than he contributes by his professional skill. In any walk in life the practice of psychiatry is one of some complexity, requiring a knowledge of the mores, laws and habits of the community in which the individual resides and works. The Navy, regarded as a community, is very large, widely scattered, autocratic by military necessity, with a great complexity in its functions of movement, communications and interpersonal relationships. If one is not familiar with these facts, one's effectiveness may be seriously hampered, and inefficiency and waste will occur.

It is first to demonstrate the foregoing statements and second to remedy these potential difficulties that the course has been instituted. In addition, it should be pointed out that the newer men in the service do not know those with whom they are working, nor are they known to those in authority, and the course of training effectively solves both of these problems. The opportunity to evaluate the doctor himself as to his fitness to perform his duties and to place him in the most advantageous location with regard to his ability and aptitude is an important part of the plan of instruction.

It should be pointed out that the new civilian doctor in the Navy has had no military experience whatever. He must learn the rudiments of military life. Even his clothing offers a considerable problem, to be out of uniform is not only to be subject to ridicule but also to commit an unconsciously embarrassing infraction of military regulation. Learning to wear a uniform is not the least of his troubles. In addition he must quickly conform with many other customs of the military services, the courtesies, the manner of saluting, his obligation in regard to those both under and over him in rank. Much time and confusion is saved by having these matters presented didactically rather than to have him learn the "hard way" and possibly have the loss of self esteem which might result from failure at some post because of his inability to adjust quickly to military procedures. It should be emphasized that a medical officer in the Navy has many duties other than those of a strictly professional character. A reality which must be faced is that these necessities hold good no matter what the physician's standing in a professional way in civil life and no matter what his rank on reporting for active duty in the Navy.

SCOPE OF TRAINING

The course of training at the present time consists of a six to eight weeks period. This is divided between didactic instruction and teaching by actual experience with case assignments. In addition to the lectures covering military necessities, professional problems for their own sake, as well as their relation to naval psychiatric procedure, are being met in this course of instruction. Staff conferences are held frequently and are attended by the regularly assigned neuropsychiatric staff and by the indoctrination class. At these conferences, patients are presented by the individual to whom the case is assigned. The diagnosis, method of management and disposition are determined and thoroughly discussed where the newly commissioned officer can see at first hand the manner of handling the specific problems. The regulations governing the commitment of institutional cases are taught by this method, as well as the important problems relating to the return of persons

not needing institutional care either to civil life or to military duty. In this respect military psychiatry cannot be as idealistic or as free as that in civilian life. This is an important lesson and one not always easily learned by the civilian physician. The unfit must be sought and removed from military service because of the great danger which might result from their retention from idealistic or sentimental reasons. This is one of the unpleasant duties of the military psychiatrist and must be performed in good faith as a part of his obligation to the service. The manner of doing this can be learned only by practical experience and demonstration, not by theoretical discussion. Thus the case in staff conference serves the purpose of showing the manner of keeping records, handling patients and reaching psychiatric decisions under wartime conditions.

In addition, the physicians under instruction are given an opportunity to question the patient as well as to express opinions regarding the case under discussion. It is here that the maturity of judgment, professional skill and military adaptability of the physicians in the group can best be evaluated, leading to careful organization of the future psychiatric services of the Navy. It has also served another interesting and valuable purpose. This might be described as the pooling of varied skills, techniques, procedures and attitudes from many clinics, hospitals and schools in various parts of the country toward a common end, i. e., a coordinated, well integrated psychiatric effort throughout the Navy. It is, of course, well known that the practice of psychiatry has many facets, depending to some extent on the phase of psychiatry practiced by the individual doctor. The attitude of teachers, state hospital administrators, analytically trained psychiatrists, those in private practice and others engaged in preventive or educational aspects of this many sided specialty may under such conditions as these become more firmly welded into a well integrated, unified specialty. It is to be hoped that the throwing together of many psychiatrists from many parts of the country, from different clinics and representing many so-called schools of thought will develop a greater tolerance and understanding of psychiatric problems in general, leading to a more effectively coordinated program, which should have a far reaching effect on the war effort as a whole.

Outside the conference, the psychiatrist from civilian life is given an opportunity to study case records and medical surveys and to do neuropsychiatric consultations for other departments in the hospital. It is particularly important that the function of the medical survey boards in the Navy, their manner of being conducted and the final recording of these be learned if a smooth working organization is to be effected. The obligation of the naval psychiatrist to other naval courts and boards and his relation to medicolegal problems are stressed in the present indoctrination course.

The importance of records from a statistical standpoint, provided they are adequate and meet reasonably uniform requirements, cannot be lightly passed over. These features are being met under the present plan, the physician not only learns how he must keep his records but is also given the opportunity to ask "why" and to obtain an answer. Thus physicians who have worked under many different systems of keeping records, no doubt all good, are standardized sufficiently to prevent a chaotic state of affairs which might preclude the possibilities of any advances in our knowledge from statistical records both during and after the war.

ADVANTAGES OF THE PLAN

It is also true that the naval psychiatrist cannot, because of military necessity, limit his practice as sharply as in civil life. Under certain conditions of warfare he might find himself required to assume the role of general practitioner. One of the advantages of the present plan of indoctrination is that each doctor is required to stand watch as Junior Officer of the Day, under instruction in these duties. Cases, other than psychiatric are seen with proper assistance and supervision, which acts as a short refresher course in general practice. Also on these occasions the physician learns many principles of administration of a naval hospital and learns to meet the many problems which may arise under such conditions. Under the present plan of instruction the civilian psychiatrist not only learns the military organization and administration of a naval hospital but is given an opportunity to perfect his knowledge of the organization of a psychiatric service in a naval hospital. This is particularly important because, if the civilian physicians are assigned to the newly commissioned naval hospitals without any knowledge of the proper responsibilities in organization and administration, great confusion can result. It should also be emphasized that the entire program offers an answer to current criticisms from the medical profession as a whole as well as from the public that psychiatrists have become too highly specialized, too detached and theoretical. The constant association with members of the profession in other specialties should have a salutary effect on the practice of psychiatry and should prove of great value in furthering our knowledge of psychosomatic medicine, and the integration of psychiatric thought with that of more general medical fields. The cloistered life of many psychiatrists, particularly those who have spent many years in institutions devoted almost solely to this specialty, cannot be considered advantageous, nor is it a small problem when the adaptation of the physician to well organized military medical efforts is immediately necessary. The dependence of the psychiatrist in civil practice on his secretary as well as on many technicians in many fields is well known. The reality of military psychiatry brings the physician face to face with the necessity of becoming within himself physician, psychiatrist, at times secretary, as well as his own social service worker under many conditions which he will meet. And he must be prepared to function as effectively as possible with at times a minimum of assistance of any kind from any source.

Regular inspections afford the psychiatrist under instruction an opportunity to learn of his future responsibilities in regard to property and its care, the practical application of the principles of sanitation and the duties which may devolve on him later as an officer responsible for these problems as well as those of personnel.

The indoctrination group further acts as a pool of medical officers, with psychiatric training, from which higher authority in the Navy may draw those who in many parts of the world will be needed for the important and varied duties of a naval psychiatrist.

Another factor of great importance has developed during the course of instruction. From time to time officers from actual combat zones have been present. The participation of these officers in the lectures and discussion serves the very practical purpose of keeping the instruction from becoming too theoretical. It has also been a policy of the Navy to bring into the hospital naval officers of little or no psychiatric training for

postgraduate instruction in psychiatry. These courses are of longer duration and the presence of these officers frequently brings in reports of practical problems in the combat zones.

There is no possibility at the present time of evaluating fully the effects of this educational plan. It may be hoped, however, that some or all of the following effects will be noted: 1. Coordination of the psychiatric effort throughout the Navy by the achievement of uniform attitudes, practices and records. 2. The elimination of technical and clerical errors, thereby minimizing unnecessary correspondence and delay in handling cases which will inevitably result if untrained civilians are "turned loose" without preliminary indoctrination. 3. More efficient application of each physician's own talent and ability from personal, first hand knowledge of these qualities by naval authorities. 4. Improvement in morale and cooperation because of personal friendship developed during the training course not only between civilians but between the newly commissioned

reserves and the veteran medical officers of the Navy. 5. Reduced man failure in the combat forces as a result of uniform standards from a military standpoint as to who is unfit for military service from a psychiatric standpoint. 6. Advances of our knowledge of psychiatric wartime problems by the achievement of uniform and valid statistical information. It should be pointed out that each of these psychiatrists who goes out from his instruction course acts as a teacher of proper naval psychiatric procedure and method.

RESULTS TO BE OBTAINED

At the present time the changes in attitude and performance of those under instruction, the high morale and spirit of cooperation between experienced naval officers and newly commissioned reservists give promise that these results will be obtained. Further application and study of the plan will be continued leading to a more complete report of the progress of military psychiatry in the Navy.

CIVILIAN DEFENSE

PROTECTION AND MAINTENANCE OF PUBLIC WATER SUPPLIES

The Medical Division of the United States Office of Civilian Defense, Washington, D. C., has published Sanitary Engineering Bulletin No. 1 entitled 'Protection and Maintenance of Public Water Supplies Under War Conditions'. The bulletin outlines a cooperative plan of mutual aid for water works, describes the functions of participating officials and suggests specific measures for consideration by local water works to the end that water service may be maintained during an emergency. The plans and suggestions in this bulletin necessarily are general as no detailed plan could be devised suitable for general adoption without modification because the functions and laws of state agencies and local communities are not uniform in the various states and because water supply installations vary. The bulletin points out that state or local programs already in operation should not be changed to conform with recommendations in this bulletin unless they will make them more effective. However, it is desirable that a uniform plan of organization be adopted and the suggestions presented in this bulletin may serve as a guide. Among other data is a table from which may be computed the amount of chlorine compounds needed to disinfect water mains temporarily out of service because of disaster. In an appendix are the precautions to be taken with the home water supply. The bulletin also has several pages of references to other literature on the protection and maintenance of public water supplies.

AIR RAID SHELTERS IN BUILDINGS

The Office of Civilian Defense, Washington, D. C., has issued a pamphlet prepared under the direction of the chief of engineers of the Army with suggestions of the National Technological Civil Protection Committee on the subject "Air Raid Shelters in Buildings". It lists the type of weapons used in air attack: incendiary bombs, gas bombs, aerial mines, aerial gunfire and high explosive bombs. The last type of weapon is subdivided into armor piercing, semiaarmor piercing, fragmentation and general purpose bombs. The bulletin points out the damage caused and the requirements for protection in buildings against these weapons. It suggests plans for shelter locations and accommodations inside and outside of buildings of different kinds and gives examples of problems with suggestions about how they may be worked out. The bulletin contains numerous diagrams of portions of buildings with suggestions about how to protect the entrances where to locate escape tunnels, how to strengthen rooms, how and where to construct separate shelters for residences, and where to dig trenches with relation to existing foundations.

THE PLUMBER IN CIVILIAN DEFENSE

In a presentation in the training course for plumbers and engineers given at the School of Public Health, University of Michigan, Ann Arbor, September 22, William H. Cary Jr., sanitary engineer (R) U. S. P. H. S., said, concerning the civilian defense program, that plumbers assigned to water utility repair squads will be called on for a variety of duties in case of enemy action. For example, auxiliary water supplies will need chlorination and we shall have to use the machines now installed in laundries, swimming pools and industries. Water possibly may have to be distributed with trucks and, while street flushers would be suitable for this purpose, they will need piping from which the householder can draw water. It may be necessary to install emergency cross connections to supplement the water supply, and even such auxiliary sources of water supply as swimming pools and industrial supplies may have to be connected to the distributing system if water plants are put out of use, and here the installation of emergency chlorinators becomes important. The selection of auxiliary workers for civilian defense work requires proper identification, a careful personal history and team practice in order to insure smooth performance. Plumbers, Mr. Cary said, have a substantial role in civilian protection.

CIVILIAN DEFENSE INSIGNIA

The director of the Office of Civilian Defense, James M. Landis, has issued Supplementary Order No. 2 (Revised), dated October 23, which cancels Supplementary Order No. 2, dated May 28, with respect to specifications and use of official articles of identification embodying the civilian defense insignia. The order sets forth the articles that may be worn and used by the civilian defense workers, such as arm bands, buttons for uniforms, emergency vehicle pennants, identification cards and signs, flags and banners, air craft, helmet, lapel and automobile emblems, pilot and observer wings, and badges.

EMERGENCY BASE HOSPITAL BEING ORGANIZED AT DURHAM, N. C.

Dr. Fred M. Hanes, Florence McAlister professor of medicine at Duke University College of Medicine, Durham, N. C., has been appointed director of the Durham Emergency Base Hospital Unit for the protection of the civilian population during the war. Dr. Hanes will hold a commission in the U. S. Public Health Service with the rank of senior surgeon. This unit which will consist of fifteen physicians, all of whom will be commissioned in the Public Health Service, inactive status, subject to call "only in grave emergency," will be one of four organized in North Carolina for this purpose, the others being in Winston-Salem, Charlotte and Raleigh.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

The *Deutsche Zeitung in Kroatian* of July 15 reports that a special department has been opened for prisoners (polizeihäftlinge) in the Foundation Hospital on the Rebrow in Zagreb, with 60 beds. This is the first department of this kind in the country and at the same time the most modern in southeastern Europe.

The *Giornale di Medicina Navale e Coloniale* of November-December 1941 contains an article by Dr. Conti, the Reich health leader, on the state of health and health services in 1940-1941. There has been no increase in epidemics and no excessive fall of the birth rate. Births in 1940 were 12,000 in excess of 1939, and the figures for 1941, as far as they are known, are hopeful, as they have remained stationary or even show a slight increase. Infant mortality has continuously decreased since 1933, but the severe winter of 1939-1940 was responsible for a slight rise from 6 per cent in 1939 to 6.30 per cent in 1940. An increase in the number of cases of scarlet fever occurred, but there was only a slight increase in fatal cases. The figures for whooping cough, infantile paralysis and meningitis all show a decrease. Other infectious diseases in 1940 were dysentery (no epidemic) 12,790 cases, typhus and paratyphus (no epidemic) 7,339 cases and petechial typhus 8 cases (5 from Poland).

The general mortality rate was 12.5 per cent. This figure, however, cannot be verified, as the exact number of deaths at the front cannot be given.

Conti then writes of the health services for repatriated Germans in Volhynia, Galicia and other provinces. In Lodz, for instance, 150 doctors and obstetricians and a staff of about 300 nurses, 180 assistants, disinfectors and pharmacists are working. About 4,000 people pass daily through the delousing centers in Lodz. Other observation centers are staffed by 600 doctors and 15,000 assistants, and these as well as camps for settlers on their way east have dealt with 40,000 cases of infectious diseases, of which 2,900 were fatal.

The smallness of the increase in tuberculosis from 80,000 to 90,000 cases a year was due to the widespread use of X-ray examinations. The mortality rate increased slightly from 7 to 8 per thousand inhabitants. Dental troubles increased but were counteracted by propaganda for the consumption of wholemeal bread. Nervous diseases increased, particularly stomach troubles. This was due to the abuse of smoking. Rheumatic troubles decreased because people were taught the importance of light, air and sun bathing, and also Sauna baths. A German inventor at Kiel has produced dried milk in lumps weighing 5 "g" each, which will keep fresh for six months, according to *Transocean* of August 22. Milk in this form will take less room than a similar quantity of powdered milk. Patrons of restaurants will be able to get dried milk in cubes in the same form as lump sugar. A lump weighing 5 "g," it is said, will make about one eighth of a quart of milk.

According to *Arbeteian* of August 19, 10,000 Karelians had returned from the Karelian Isthmus and were living in cardboard barracks six to eight families in a barrack, with only one fireplace. The barracks are leaky in wet weather and are beginning to disintegrate. Some families were living in cellars, threshing sheds and dugouts.

RED CROSS APPEALS FOR NURSE-
INSTRUCTORS

A call for members of the Women's Auxiliary who are retired nurses to serve as home nursing instructors was issued at a recent meeting of the National Council on Red Cross Home Nursing. A quota of 1,000,000 persons successfully completing Red Cross home nursing instruction during the year ending June 30, 1943 was set by the council.

"If we are to fill our quota we shall need many new instructors, who must be registered nurses," said Mrs. Ross T. McIntire, wife of the Surgeon General of the United States Navy and a member of the council. "For nurses who retired to marry doctors this is a most suitable way to contribute to the war program. Many, of course, are returning to at least part time active nursing. Those who find home responsibilities too heavy for active nursing should find time to teach a home nursing class. Retired nurses married to Army and Navy doctors are especially needed to teach in areas adjacent to

military posts, where the nursing shortage is particularly acute. No women are better aware of the desperate shortage of nurses than doctors' wives, and none see the need of families for some nursing instruction as well as we do."

A typical nursing program carried on by doctors' wives is that of the Washington, D. C., auxiliary. Mrs. A. Magruder MacDonald, president, reports that a majority of its nurse-members have gone back into nursing and are serving in overburdened Washington hospitals. Many others are acting as home nursing instructors. Members of the auxiliary recently formed a Red Cross Home Nursing class and many members are Red Cross nurses aides. A great number have also donated to the Red Cross blood donor service.

COURSE IN OCCUPATIONAL DERMATOSES

A combined lecture and demonstration course in occupational dermatoses will be conducted in Chicago, beginning Jan. 11, 1943, by Dr. Louis Schwartz, chief of the dermatoses Investigations Section of the U. S. Public Health Service. The teaching period will cover two weeks, the first of which will be devoted to lectures and demonstrations and the second to plant visits. Dermatologists, industrial physicians and others interested in the course should communicate with Dr. Edward A. Oliver, 55 East Washington Street, Chicago. No limit will be placed on enrollment for the lectures, but the visits to the plants will be limited to twenty-four enrollees. No fees will be charged.

NURSES AIDES FOR VETERANS
HOSPITALS

The administrator of veterans affairs, Brig. Gen. Frank T. Hines, has requested of the American Red Cross that it assign volunteer nurses aides for service in the veterans hospitals. The Red Cross has issued a memorandum for transmission to local chapters authorizing such assignment but pointing out that they must receive their training in civilian hospitals. Requests for this service should be sent to the Red Cross area office, which will attempt to secure volunteers for these assignments. Since under the law of the Veterans Administration nursing service must be paid for, arrangements have been made for nurses aides in veterans hospitals to be paid at the rate of \$1 a year and the Veterans Administration is prepared to furnish quarters, meals and laundry, when necessary. These aides must be American citizens.

RESURVEY OF PROFESSIONAL
NURSES

To explore the adequacy of the nation's nurse power in the present critical shortage a resurvey of all professional nurses in the United States is being initiated by the Subcommittee on Nursing, Office of Defense Health and Welfare Services. Paul V. McNutt, Federal Security Administrator, announced on November 10.

In preparation for launching the survey a meeting of all state agents for the inventory was called for November 13 at the National Institute of Health, Bethesda, Md. These special agents, appointed by the U. S. Public Health Service, also are representatives of the state nursing councils for war service. The survey, to be conducted by the U. S. Public Health Service, will bring up to date the inventory of nurses taken in January 1941 and include about fifty thousand nurses who have graduated from accredited schools of nursing in the last two years. It will be carried on in close cooperation with professional nursing organizations and local Red Cross nursing committees.

Miss Pearl McIver, principal nursing consultant of the U. S. Public Health Service, said that "all registered nurses and all graduate nurses who are inactive and have let their registration lapse are being urged to participate in the survey." Post cards will be mailed by state agents to every nurse in their respective states. Tabulated data furnished by those responding will be compiled by the states and sent to the U. S. Public Health Service in Washington. Individual cards will be retained locally for use of local nursing councils for war service in planning an equitable distribution of nurses to meet military and civilian needs.

ORGANIZATION SECTION

OFFICIAL NOTES

REPORT OF MEETING OF THE COUNCIL ON MEDICAL EDUCATION AND HOS- PITALS HELD IN CHICAGO, NOV 8, 1942

For the duration of the war the Council made certain recommendations with regard to premedical education. These recommendations were published in THE JOURNAL, November 14, page 850.

The University of Georgia School of Medicine was restored to the list of approved medical schools maintained by the Council on Medical Education and Hospitals with the status of being on probation. A statement regarding this action was likewise published in THE JOURNAL, November 14, page 850.

The Council recommended that the "Essentials of an Acceptable School for Clinical Laboratory Technicians," Section III, Faculty, paragraph 2, first sentence, be modified to read: "In laboratory practice the enrollment should not exceed two students to each member of the teaching staff."

The Council recommended that the "Essentials of an Acceptable School for Clinical Laboratory Technicians" be modified to read:

V REQUIREMENTS FOR ADMISSION

13. Candidates for admission should be able to satisfy one of the following requirements:

- Graduation from an accredited school of nursing
- Graduation from an accredited school of physical education
- Two years of approved college training including satisfactory courses in biology and other sciences

Courses in general physics and chemistry, as well as biology, are highly recommended for all who seek to enter training in physical therapy.

The Council at this meeting took action as follows regarding hospitals for intern training and for residencies and fellowships, as well as schools for the training of clinical laboratory and physical therapy technicians:

Hospitals Approved for Internships

Jefferson Hospital, Birmingham, Ala.
Woman's Hospital, Detroit
McKeesport Hospital, McKeesport, Pa.

RADIO BROADCASTS

"Doctors at War"

American Medical Association dramatized radio broadcasts in cooperation with the National Broadcasting Company will be resumed Saturday, December 26, at 5 p. m. eastern time (4 o'clock central time, 3 o'clock mountain time, 2 o'clock Pacific time). The title of the new series will be "Doctors at War: Book III of Doctors at Work."

Doctors at War will be broadcast with the official approval and cooperation of the Medical Department, United States Army, and the Bureau of Medicine and Surgery, United States Navy. Rear Admiral Ross T. McIntire, Surgeon General of the United States Navy, will appear on the program on a selected date. The broadcasts will be a continuation of the story of Doctors at Work, carrying the fictitious but typical American physicians into the military and naval services of the United States and following the development of the practice of medicine in typical American communities affected by industrial expansion, troop training programs and other wartime influences.

As in past years, the program will be dramatized. Scripts will again be written by William J. Murphy, continuity editor, central division, National Broadcasting Company. Production direction, actors and music will be from the broadcasting company staff. Time is donated and production costs are shared by the National Broadcasting Company.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

Pediatricians Elect Officers—Dr Amos C Gipson, Gadsden, was elected president of the Alabama Pediatric Association at its recent annual meeting in Birmingham, succeeding Dr Clifford L Lamar, Birmingham, Dr John Sam Smith, Montgomery, was named vice president, and Dr Ruth F R Berrey, Birmingham, secretary-treasurer

ARKANSAS

Society News—The Northeast Arkansas Medical Society was addressed at Jonesboro, October 8, by Drs Joe Verser, Harrisburg, on "Histamine, In the Specific Type Head Ache and Meniere's Disease", Isaac G Duncan, Memphis, Tenn, "Carcinoma of the Prostate", and Joseph F Shuffield, Little Rock, industrial surgery. Comdr Homer A Higgins, Little Rock, state medical officer, Selective Service, also spoke.—The Third Councilor Medical Society was addressed in Forrest City October 22, by Drs Lucius C Sanders, Memphis, Tenn, on "Diagnosis and Treatment of Gout", Arthur G Quinn, Memphis, "Infantile Paralysis", Gilbert J Levy, Memphis, "The Kenny Treatment of Infantile Paralysis", Rufus B Robins Camden, and Comdr Homer A Higgins, M C, U S Navy Reserve, Little Rock

GEORGIA

Personal—Dr William R Richards, formerly of Calhoun, has been named health commissioner of Greene County, Greensboro, effective July 1

New State Appointments—Dr Frank M Ridley Jr, La Grange, was recently appointed a member of the state welfare board to succeed Dr Wallace K Smith, Pembroke, who resigned to accept an appointment on the state board of medical examiners. Dr Smith succeeds Dr Robert F Wheat, Bainbridge. Dr Farish C Holden, Atlanta, was named a member of the board of medical examiners, succeeding Dr Harold P McDonald, Atlanta

District Meeting—The semiannual meeting of the Fifth District Medical Society was held at the Academy of Medicine, Atlanta October 19. Speakers included Major Donald T Chamberlin, M C, U S Army, "Functional Digestive Diseases as Encountered at the Lawson General Hospital", Major Joseph J Wallace, M C, U S Army "The Arthritic Problem as Viewed at the Lawson General Hospital", and Major Walter M Bartlett, M C, U S Army, "Three Thousand Hours of Cardiovascular Diseases in a General Hospital"

Dr Boland Named Professor of Surgery—Dr Frank K Boland, professor of clinical surgery at Emory University School of Medicine, Atlanta, has been appointed Joseph B Whitehead professor of surgery at Emory. He succeeds Dr Daniel C Elkin who resigned to take up military duties at Walter Reed General Hospital, Washington, D C. The Whitehead professorship was created in 1939 under a grant from the Joseph B Whitehead Foundation of Atlanta and carries a special endowment for research and teaching. Dr Elkin was the first incumbent of the chair

IDAHO

Public Health Meeting—A H Christiansen, Boise, was elected president of the Idaho Public Health Association at its annual meeting at the University of Idaho, Southern Branch, in Pocatello, October 12-13, and H C Clare, M S Eng, Boise, is secretary. Among the speakers at the meeting were John R Nichols, executive dean, on public health in the war effort, Dr Paul D Mossman San Francisco, relationship between Army and Navy health agencies, Dr Fred T Foard San Francisco, emergency medical services, and Dr Ernest L Berry Boise, state director of public health

ILLINOIS

Society News—Dr Raymond W McNealy, Chicago discussed diseases of the gallbladder before the Adams County Medical Society at Quincy November 10.—At a meeting of the Will-Grundy Counties Medical Society in Joliet, November 13, Dr Frederick H Falls Chicago, spoke on "Management of Prolonged Labor".—The Macon County Medical Society was addressed in Decatur November 17 by Dr Edward D Allen, Chicago, on gynecology

Chicago

The Bacon Lectures—Dr Edward A Schumann formerly professor of obstetrics, University of Pennsylvania School of Medicine Philadelphia, will deliver the Charles Summer Bacon Lectures for 1942-1943 at the University of Illinois College of Medicine, December 2-3. His subjects will be "The Chamberlains and the Obstetric Forceps" and "Tuberculosis Involving the Female Genitalia"

Cancer Prize Awarded to Dr Huggins—Dr Charles B Huggins, professor of surgery (urology), University of Chicago School of Medicine has been awarded the Catharine Berkan Judd Prize of \$1,000 for his development of a "method of treatment for prostatic cancer". The Judd Prize was established in 1937 and is administered by the board of directors of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York. It is awarded annually for outstanding research in the field of cancer

Dr Windle Named Director of Neurologic Institute—William F Windle, Ph D, professor of microscopic anatomy at Northwestern University Medical School, has been appointed professor of neurology and director of the Neurologic Institute to succeed the late Dr Stephen W Ranson. Horace W Magoun, Ph D, associate professor of neuroanatomy, has been named professor of microscopic anatomy to succeed Dr Windle. Other advancements include Barry J Anson, Ph D, to professor of anatomy and Dr Paul B Magnuson to professor of bone and joint surgery and chairman of the department

KANSAS

Personal—Dr Walter N Mundell, Hutchinson has been named health officer of Reno County.—Dr Herbert R Schmidt, Newton, has been appointed coroner of Harvey County to succeed Dr Charles T Sills, who recently entered the army. Dr John E Attwood, La Crosse, has been appointed coroner of Rush County to succeed Dr Joseph H Baker, who also entered the army.—Dr Harry J Deeths has been appointed health officer of Atchison

Outbreak of Bacillary Dysentery—In September three thousand persons in Newton were afflicted with an intestinal disorder which has since been proved to be bacillary dysentery. It was established that the contamination came from the Mexican village in the city where the water mains were being repaired near the water storage tanks of the city water supply. According to the state medical journal, the outbreak involved 35 per cent of the population of Newton

The Porter Lectures—Dr Irvine McQuarrie, professor of pediatrics, University of Minnesota Medical School, Minneapolis, delivered the twelfth course of lectures under the Porter Lectureship in Medicine at the University of Kansas School of Medicine, Kansas City November 3-4. The first and third lectures were given at the medical school in Kansas City and the second lecture in the Fraser Theater at Lawrence. Titles of Dr McQuarrie's lectures were "Experiments of Nature and the Advancement of Medical Knowledge," "Medical Experiences in Besieged China" and "Diseases of Adrenal Glands in Children"

LOUISIANA

Postgraduate Course—Tulane University of Louisiana School of Medicine, New Orleans announces a course in traumatic and emergency surgery November 30-December 1-5 and one on pediatrics January 25-28. The first course will cover shock, facial injuries, amputations, burns, skin grafting hand injuries, abdominal, thoracic and vascular injuries back injuries fractures head injuries and the sulfonamides. The course on pediatrics will include a discussion of infant feeding care of normal newborn and premature infants, blood dyscrasias, infectious diseases, heart disease intestinal parasites and the child in relation to war

MARYLAND

Health District Ten Years Old—The Eastern Health District of Baltimore, which started as an experimental unit has completed ten years of service. The district was the first organized to provide public health service in Baltimore on a neighborhood basis. Since it was established, the Western Health District and the Southeastern Health District have been created. Dr Harry S Mustard New York, was health officer of the Eastern district for the first five years and since his resignation in 1937 Dr Charles Howe Eller Baltimore has been in charge. The establishment of the unit was a recommendation of Dr Joseph W Mountin Washington D C in his report on the public health survey of Baltimore and grants from the Rockefeller Foundation assisted in its development

MASSACHUSETTS

Birth Control Amendment Rejected—Massachusetts voters rejected a birth control amendment which would have permitted physicians to give contraceptive advice to married persons as a health measure, according to the New York Times November 4

Emeritus Professors at Harvard Called Back—The following five emeritus professors at Harvard Medical School, Boston, have been called back into active service: Drs David Cheever, Henry A Christian, John Homans, Franklin S Newell and William C Quinby all of Boston. According to the *Harvard Medical Alumni Bulletin* Dr Cheever took over the position of surgeon-in-chief at the Peter Bent Brigham Hospital July 15 in the absence of Dr Elliott C Cutler, Boston who has gone into army service

Physician Receives Publisher's Award—Dr Frederick C Irving since 1934 William Lambert Richardson professor of obstetrics at Harvard Medical School, Boston and visiting obstetrician since 1931 at the Boston Lying-In Hospital, has received the fourth award of the Houghton Mifflin Company in its Life-In-America series for his book entitled 'Safe Deliverance'. The book was published early this month. The Houghton Mifflin awards in this Life-In-America series were first started in 1941. The prize consists of \$2500.

Professor Lamb Awarded Nichols Medal—The 1943 William H Nichols Medal of the New York Section of the American Chemical Society was presented to Arthur B Lamb Ph.D. Erving professor of chemistry dean of the Graduate School of Arts and Sciences and director of chemical laboratory Harvard University Cambridge. Professor Lamb for twenty-five years editor of the *Journal of the American Chemical Society* was cited as an authority on inorganic chemistry, as 'an investigator and administrator who has earned a permanent place of honor in the world of science' particularly for research into the properties of aquo and ammonio metal salts.

Industrial Problems in Medical Practice—A postgraduate institute entitled 'Industrial Problems in Medical Practice' was held at the Harvard Club November 7 under the auspices of the state medical society. Among the speakers were:

- Dr Daniel L Lynch Boston The Value of Preemployment Examinations
- Commander A Warren Stearns M.C.U.S. Naval Reserve Boston The Personality of Industrial Applicants
- Dr Alan R Moritz Boston Toxic Fumes and Gases in Industry
- Dr John G Downing Boston Industrial Dermatitis
- Lieut Comdr Edwin B Dunphy M.C.U.S. Naval Reserve Boston Injuries to the Eyes
- Dr Frank R Ober Boston Examination and Diagnosis of Lane Back Conditions
- Lieut Col Anthony J Lanza M.C.U.S. Army Arlington Va Responsibility of Physicians to Industry in Winning the War
- Dr Carl W Walter Boston Sterilization in Operating Rooms

A round table discussion on the treatment of burns was held by Drs Edward D Churchill, S Howard Armstrong Jr Oliver Cope and Charles C Lund and one on the modern treatment of wounds by Drs Champ Lyons, Henry C Marble, Joseph H Shortell and Gordon M Morrison, all of Boston.

MINNESOTA

Financial Gifts to University—Gifts totaling more than \$100,000 have been accepted by the board of regents of the University of Minnesota Minneapolis, and include the following:

- \$10,700 from the National Foundation for Infantile Paralysis for continued study of the biochemical and physiologic aspects of infantile paralysis
- \$10,000 from the National Foundation for Infantile Paralysis to be used for the support of Sister Kenny's work and for the continuation of the instructional program in the Kenny technique
- \$10,410 for Minneapolis General Hospital fellowships
- \$1,800 for Minneapolis General Hospital pediatrics directorship
- \$10,000 from the Home for Children and Aged Women to support the Children's Psychiatric Clinic
- \$7,000 from the National Research Council for research on fat metabolism under the direction of Dr Arild E Hansen department of pediatrics
- \$5,160 from the U.S. Public Health Service for the support of a training program for nurse anesthetists
- \$4,000 from the W.K. Kellogg Foundation to establish a loan fund in the school of nursing
- \$3,000 from Sharp & Dohme Inc. for researches on sulfonamides and in chemistry by Richard T. Arnold and William G. Clark
- \$1,200 from the Josiah Macy Jr. Foundation for support of a study on mechanism of the action of sex hormones being made by Leo T. Samuels Ph.D. of the department of physiology
- \$1,200 and \$1,063 from the Rockefeller Foundation for British medical student fund
- \$1,000 from the Winthrop Chemical Company to establish research on pyocyanine and other related chemotherapeutic agents under Dr Joseph T. King of the department of physiology

MISSOURI

Medical Plan for Wives and Infants of Service Men—The division of child hygiene of the state board of health and the U.S. Children's Bureau, Washington, D.C., is initiating a medical and hospital obstetric and pediatric care program in Missouri for the families of the men in the armed forces. The program will subsidize the services of the local medical practitioner on a case basis and in a small way repay him for such service. When hospitalization is necessary for the safety of the mother and newborn child and sick children, such care will be paid for under this program. Funds are available at present to carry out this program to a limited degree, and additional funds are being requested from the Children's Bureau so that a complete medical and hospital obstetric and pediatric care program may be worked out on a statewide basis. The program is being worked out with the cooperation of all physicians in the state who are registered with the board of health, insuring the patient the choice of physician.

MONTANA

Dr Cox Goes to Lederle Laboratories—Herald R. Cox, Sc.D. chief bacteriologist at the Rocky Mountain laboratory, U.S. Public Health Service, Hamilton, and president of the Montana State Public Health Association, has accepted a position as associate director of research for the Lederle Laboratories Pearl River N.Y., according to the *Journal of the American Medical Association*. He will have charge of all virus disease work. Dr Cox joined the staff of the Rocky Mountain laboratory as associate bacteriologist in 1936 and was promoted to chief bacteriologist in 1940. He received his doctor of science degree at Johns Hopkins University, Baltimore, in 1931. From 1932 to 1936 he was assistant in pathology and bacteriology at the Rockefeller Institute for Medical Research. The 1940 Theobald Smith award in medical science consisting of a bronze medal and \$1,000 established by Eli Lilly & Company in 1935 was presented to Dr Cox for his research in the rickettsial diseases resulting in the development of a new technique for the preparation of protective vaccines against Rocky Mountain spotted fever and typhus fever.

NEW JERSEY

Hospital News—The cornerstone of the new St. Michael's Maternity Hospital, Newark, was recently laid the occasion being the seventy-fifth anniversary of the hospital. The new Maternity Building will accommodate 85 beds and increase the hospital's total to 455.

Society News—Dr John A. Kolmer Philadelphia discussed 'The Sulfonamide Compounds in the Prophylaxis and Treatment of Disease' before the Gloucester County Medical Society in Woodbury recently. The Essex County Medical Society was addressed November 12 in Newark by Dr Philip M. Stimson New York on 'Early Treatment of Polymyositis with a Demonstration of the Kenny Technique'.

NEW YORK

Forum on Kenny Treatment—The Westchester chapter of the National Foundation for Infantile Paralysis will sponsor a meeting November 24 at the New York Hospital, Westchester Division White Plains, in cooperation with the Medical Society of the County of Westchester. The session will be devoted principally to a demonstration of the Kenny method for the treatment of infantile paralysis. Dr Frank M. Wright, New Rochelle will discuss the subject from the point of view of the physician. Mrs. Eleanor W. Kirban, R.N., Grasslands Hospital, Valhalla, the nursing aspects, and Miss Lucy Lewandowska, R.N., of the county health department, the physiotherapeutic aspects. Dr. Don W. Gidakunst, New York, medical director of the national foundation, will conduct a question period.

New York City

Dr Opie Returns to Active Status at Cornell—Dr Eugene L. Opie, who became emeritus professor of pathology at Cornell University Medical College in 1941, has returned to the active direction of the department during the absence of Dr William Dock, who has been commissioned a major in the army. Dr Opie will continue research studies which he has been conducting at the Rockefeller Institute for Medical Research since his retirement from Cornell.

Friday Afternoon Lectures—The New York Academy of Medicine opened its annual series of Friday Afternoon lectures, November 6, with a talk by Dr David P. Barr on "Disorders of the Hypophysis from a Clinical Standpoint".

Dr Harry Gold spoke November 13, on "Recent Advances in Therapeutics, Including the Newer Drugs of the Sulfonamide Group." Others in the series include Drs Gerald H Pratt, November 20, on "The Surgical Treatment of Circulatory Disorders in the Lower Extremities, Including Diabetic Gangrene", Alvin F Guttmaacher, Baltimore, December 4 "The Role of Artificial Insemination in Treating Human Sterility", Hobart A Rimmann Philadelphia, December 11, "Virus Pneumonia" and Henry W Cave, December 18, "Peritonitis Conservative Treatment"

Dr Sachs Honored—Special exercises will be held at Mount Sinai Hospital, November 24 for the presentation to Dr Bernard Sachs, consulting neurologist at the hospital, of a special issue of the Journal of the Mount Sinai Hospital containing scientific contributions by his friends, associates and colleagues in recognition of the valuable services he has rendered in his "sixty years of participation in the progress of medicine." Among the speakers will be

Mr Leo Arnstein president of the Mount Sinai Hospital
Dr Foster Kennedy
Dr Malcolm Goodridge president of the New York Academy of Medicine
Dr Adolf Meyer Baltimore
Mr John S Burke president of the Altman Foundation
Mr Henry Moses chairman board of trustees Montefiore Hospital for Chronic Diseases
Dr Tracy J Putnam
Dr Henry A Riley
Dr Ira Cohen

Report on Oxygen Therapy—The committee on public health relations of the New York Academy of Medicine has published a report discussing the administration of oxygen therapy. The report cited a recent announcement by William B Herlands, LLB commissioner of investigation city of New York, that inquiry by his office had disclosed that many New York physicians engaged in the "highly unethical" practice of exacting commissions or "kickbacks" from medical oxygen companies when ordering oxygen for patients. The medical committee took issue with the commissioner's report that, according to oxygen companies, "many physicians" accept commissions or kickbacks from companies which supply oxygen and oxygen therapy equipment. The practice, the committee stated, "is indulged in by a small fringe of the medical profession." It is unfortunate, the report continued, that "newspaper publicity has exploited the unethical conduct of a comparatively small number of physicians to the detriment of the entire medical profession." The names of offending practitioners, the committee stated, should be submitted to the county medical societies and the academy of medicine "for requisite disciplinary action." As a long range measure to protect the public against unnecessarily high charges, the committee agreed with Mr Herlands that companies should be required to submit a schedule of their rates to the department of health and that the department should publish the rates as a guide to the public. The committee also agreed with Mr Herlands that all oxygen therapy technicians should be licensed so that only physicians or laymen qualified through training will administer oxygen. The report recommended that the state department of education, rather than the board of health, as suggested by Commissioner Herlands, should be charged with licensing the technicians, whether they are employed by hospitals or by private concerns. "Licensure by this department," the report said, "would be more desirable than that by the city department of health, first, because it would be statewide and second because it is scarcely within the province of the department of health to supervise personnel engaged in medical therapy. In order to qualify as a licensed oxygen therapy technician, the candidate should be required to pass a course in the operation of apparatus."

OREGON

State Medical Plans Merge—On November 1 the Southern Oregon Medical Service Association became a part of the Oregon Physicians' Service, the approved statewide medical service plan sponsored by the Oregon State Medical Society. The Southern Oregon Medical Service Association is operating a prepaid medical and hospital plan for civilian employee groups.

PENNSYLVANIA

Society News—Dr Gabriel Tucker Philadelphia, addressed the Reading Eye, Ear, Nose and Throat Society, October 28, on the diagnosis and treatment of benign and malignant lesions of the larynx. —The Lackawanna County Medical Society was addressed in Scranton October 27 by Dr Michael M Wolfe Philadelphia, on Modern Methods in Facial Plastic Surgery."

Philadelphia

The Pancoast Lecture—The second Henry K Pancoast Memorial Lecture was delivered before the Philadelphia Roentgen Ray Society and the Philadelphia College of Physicians on November 5 by Dr Lawrence Reynolds Detroit on "Newer Investigations of Radiation Effects and Their Clinical Application." The lecture was established in honor of Dr Henry K Pancoast, who at the time of his death May 20 1939 was professor of radiology at the University of Pennsylvania School of Medicine, Philadelphia and the Medico-Chirurgical College Graduate School of Medicine, University of Pennsylvania.

GENERAL

Dr Kleinschmidt Named Director of Medical Service for Red Cross—Dr Harry E Kleinschmidt, formerly director of health education of the National Tuberculosis Association, New York, has been appointed director of medical and health service of the North Atlantic Area of the American Red Cross with headquarters in New York.

Advisory Committee on Infantile Paralysis—Because of the war time demands on the time of its medical advisers and others associated with the research and other scientific activities of the National Foundation for Infantile Paralysis the third annual medical meeting of the foundation will be confined to a one day meeting of the medical advisory committees, to be held December 3 at the New York Academy of Medicine New York.

Society of Anesthetists—The American Society of Anesthetists, Inc, will meet in the Squibb Auditorium, New York, December 10 under the presidency of Dr Wesley Bourne Westmount, Que, Canada. Included among the speakers will be Drs Herbert C Maier, New York on Responsibility of the Anesthetist in Reducing Operative Complications in Thoracic Surgery" and Captain Harold F Bishop, M C, Army of the United States Washington, D C, "Comparative Clinical Results Using Various Drugs and Methods in Spinal Anesthesia."

Industrial Nutrition Advisory Service—An industrial nutrition advisory service has been organized under the direction of Dr William H Sebrell Jr director of the division of chemotherapy, National Institute of Health and deputy assistant director Office of Defense Health and Welfare Services and Milburn L Wilson M S assistant director in the Office of Defense Health and Welfare Services. This service will provide practical recommendations to both government owned plants and private industries to meet specific industrial nutrition problems which may affect production by increasing accidents. Dr Robert S Goodhart New York, will direct the nutrition advisory service to industry.

Wool for Use in Kenny Treatment of Infantile Paralysis—The National Foundation for Infantile Paralysis has 100 per cent wool available for patients getting the Kenny treatment. The wool can be shipped only to hospitals where the need is immediate that is, where patients in the early stages of infantile paralysis are actually under treatment when the request is made. The material available through the cooperation of the National Paperboard Association cannot be shipped in anticipation of cases that may occur in the future. In communities where there are only 1 or 2 cases, it is suggested that sufficient material such as older blankets light weight woolen suiting and the like can be obtained without calling on the foundation's supply. According to an announcement which appeared in the New York Times an average of 5 pounds of woolen material is required for each patient. Those requesting it from the foundation are asked to order only as much as is needed.

Heart Disease Increases—According to figures from the U S Census Bureau published in the newspapers there were 385,191 deaths from heart disease in 1940 giving a rate of 292.5 per hundred thousand of population and totaling the greatest number of deaths ever recorded from heart disease. The rate per hundred thousand deaths in 1939 was 275.5. The following comparison between 1900 and 1940 shows the sharp decrease in the death rate in the low age brackets.

	1900	1940
Under 1 year	17.5	147.8
1-4 years	3.6	15.0
5-14 years	8.0	23.3
15-24 years	14.0	28.8
25-34 years	29.7	43.4

The increase in fatalities among upper age groups is shown by these figures: 35-44 years, 917 in 1940 and 808 in 1900; 45-54 years, 279.5 in 1940 and 173.0 in 1900; 55-64 years, 713.5 in 1940 and 414.1 in 1900; 65-74 years, 1,723.5 in 1940 and 957.3 in 1900 and 75 and over, 4,813.2 for 1940 and 1,819 for 1900.

Society for the Study of Asthma and Allied Conditions—The Society for the Study of Asthma and Allied Conditions will hold its fall meeting at the Hotel Plaza, New York, December 5. Among the speakers will be

- Dr. Chevalier L. Jackson Philadelphia Differential Diagnosis in Patients with Wheezing
- Dr. John A. Kolmer Philadelphia Biotherapy and Chemotherapy of the Respiratory Tract Diseases
- Dr. Matthew Brunner Brooklyn N. Y. Canine Sensitivity to Ascaris Antigen
- Dr. Stephen D. Locke East Petersburg Pa. Inhalation of Oxygen and 1:100 Epinephrine Hydrochloride Plus 5 per Cent Glycerin for Relief of Asthmatic Attacks
- Dr. Robert W. Hyde Fairfax Va. Distribution of Allergic States in Selectees
- Dr. Abraham Colmes Boston Study in Hay Fever
- Dr. Mary E. H. Loveless New York Immunological Studies of Pollinosis
- The Accelerated Immune Response in Hay Fever Patients
- Drs. Milton B. Cohen and Harold J. Friedman Cleveland Preliminary Report on the Fractionation of Ragweed Pollen and Immunological Studies with These Fractions
- Dr. Abner M. Fuchs and Margaret B. Strauss B. A. New York The Treatment of Hay Fever with Gelatin Pollen Extracts
- Dr. Joseph Harkavy New York Vascular Allergy

The Presidential Address was delivered at the luncheon meeting by Dr. Louis Tuft, Philadelphia on "Critical Evaluation of Skin Tests in Allergy Diagnosis."

Finney-Howell Research Fellowships—The Finney-Howell Research Foundation announces that all applications for fellowships for next year must be filed in the office of the foundation 1211 Cathedral Street Baltimore by January 1. Applications received after that date cannot be considered for the 1948 awards which will be made the first of March. Fellowships carrying an annual stipend of \$2,000 are awarded for one year with the possibility of renewal up to three years. When deemed wise by the board of directors special grants of limited sums may be made to support the work carried on under a fellowship. The foundation was provided for in the will of the late Dr. George Walker Baltimore for the support of "research work into the cause or causes and the treatment of cancer." The will directed that the surplus income from the assets of the foundation together with the principal sum should be expended within a period of ten years to support a number of fellowships in cancer research each with an annual stipend of \$2,000 in such universities laboratories or other institutions wherever situated, as may be approved by the board of directors. Applications for fellowship must be made on a blank form, which will be furnished by the secretary or any member of the board of directors.

Special Society Elections—Dr. Ewen M. MacEwen dean of the State University of Iowa College of Medicine Iowa City, was chosen president-elect of the Association of American Medical Colleges at its annual session in Louisville Ky., October 28, and Dr. Waller S. Leathers, Nashville Tenn., was installed as president. Dr. John Walker Moore dean of the University of Louisville School of Medicine, was chosen vice president. Dr. Fred C. Zapffe Chicago was again reelected secretary, a position he has held for forty years. The next annual meeting will be held in Cleveland, October 25-27. Present officers of the American Congress of Physical Therapy are Drs. Fred B. Moor, Los Angeles, president, Kristian G. Hansson, New York, president-elect, Miland E. Knapp, Minneapolis, first vice president, Walter S. McClellan, Saratoga Springs, N. Y., second vice president, Herbert Worley Kendall, Chicago, third vice president, Kenneth Phillips Miami, Fla., fourth vice president, Ora Leonard Huddleston Denver, fifth vice president, Richard Kovacs, New York, secretary, John S. Coulter, Chicago, treasurer, Walter J. Zetter, Cleveland, executive director and Marion G. Smith B. Se., Chicago executive secretary. THE JOURNAL (November 15 page 854) inadvertently carried the old officers in the news columns.

Meeting of Radiologists—The twenty-eighth annual meeting of the Radiological Society of North America will be held at the Drake Hotel, Chicago, November 30-December 4 under the presidency of Dr. Leon J. Menville, New Orleans. Refresher courses will be conducted throughout the meeting. In addition, the following will speak, among others:

- Dr. C. Allen Good Jr. Rochester Minn. Intussuscepting Lesions of the Small Intestine
- Dr. Charles W. Schwartz New York Pitfalls to Be Avoided in the Roentgen Diagnosis of Intracranial Disease
- Lieut. Col. Esmond R. Long M. C. U. S. Army Philadelphia and Captain William H. Stearns M. C. U. S. Army New York Standards for Army Acceptance and Their Application as Illustrated by a Review of Fifty Thousand X-Ray Films of Inducted Men
- Lieut. Comm. Chester H. Warfield M. C. U. S. Naval Reserve Wichita Kan. Types of Pulmonary Tuberculosis Which Demand Disqualification for Active Duty in the Navy
- Dr. Manuel M. Garcia New Orleans Tissue Dosage in the Control of Carcinoma of the Cervix
- Dr. Edgar C. Baker Youngstown Ohio Observations on Venography of the Lower Extremities
- Dr. Erich M. Uhlmann Chicago Practical Aspects of Tumor Clinic Management

Drs. Robert E. Fricke Rochester and Peter A. N. Pastore Richmond Va. Radium Treatment of Hypertrophied Lateral Bands of the Pharynx

Drs. Rieva Rosh and William P. Quinn New York Roentgen Rays in the Treatment of Cervical Lymphadenitis

H. M. Parker, M. Sc. Seattle A Device for the Construction of Radium Applicators

Drs. Fred J. Hodges and Isadore Lumpe Ann Arbor Mich. The Differential Response of Tissues of Neutron Radiation

Dr. Benjamin H. Orndoff Chicago Roentgen Castration for Malignant and Nonmalignant Disorders

Dr. Albert Soiland Los Angeles Plastic Induration of the Penis

There will be symposiums on atypical pneumonoma carcinoma of the cervix uteri, tumor clinics in general hospitals, correlation of disability with roentgen findings and injuries to the head, chest and back. The banquet will be addressed on Thursday evening by representatives of the army, navy and public health service.

LATIN AMERICA

Hospital News—A new emergency hospital will be erected in Natal City under the auspices of the Natal branch of the Brazilian Red Cross and local authorities on a site donated by the Society for the Aid of Hospitals in Natal City. A fund of \$11,500 has already been donated by the city.

Pan American Congress of Endocrinology—The third Pan American Congress of Endocrinology will be held in Buenos Aires, July 1-6, 1948. The headquarters of the congress are at the Instituto de Fisiologia de la Facultad de Medicina de Buenos Aires. Dr. Eduardo Braun Menendez is the general secretary.

Hospital Institute Planned—Plans for a second Latin American Hospital Institute to be held in Mexico City next May were advanced at the recent American Hospital Association convention. Modern Hospital Announces. It will be sponsored by the Inter-American Hospital Association with the cooperation it is expected of the various American hospital groups, the School of Tropical Medicine of Puerto Rico, the Office of Civilian Defense and the U. S. Children's Bureau.

Prizes for Medical Work—Dr. Amal S. Introzzi, of the Instituto de Clinica Quirurgica de Buenos Aires, was awarded the 'Mamuel A. Montes de Oca' prize for his book entitled 'Bases experimentales del tratamiento quirurgico de la hipertension arterial esencial.' The Montes de Oca Prize is given by the Faculty of Medicine of the University of Buenos Aires. Three prizes were awarded by the Comision Nacional de Cultura de Buenos Aires for medical work carried on in Argentina from 1939 to 1941 to the following doctors. The first prize was given to Dr. Jose Arce, formerly dean of the Faculty of Medicine of the University of Buenos Aires for his book 'Neumotorax Procopatorio.' Second prize went to Dr. Pablo Luis Mirizzi for his book 'Fisiopatologia del hipocholesterolico. Colonografia operatoria.' Third prize was awarded to Dr. Delfor de Valle for his book 'Patologia y cirugía del esfinter de Oddi.' Drs. Pedro Mateo Rafael Re, Atilio C. Bottini and Leon Soldati had honorary certificates for their books.

FOREIGN

Personal—Dr. Arthur William Nickle Ellis professor of medicine at the University of London was appointed regius professor of medicine at the University of Oxford on the retirement of Sir E. Parquhar Buzzard. According to an announcement in *Nature*, Sir Henry H. Dale, president of the Royal Society, has accepted a directorship of the laboratories of the Royal Institution of Great Britain with the fulltime professorship of chemistry in succession to the late Sir William H. Bragg. It was stated that Sir Henry had expressed the wish that his appointment should be limited to a period of three years.

Government Services

Government Employees Examined for Tuberculosis

The U. S. Public Health Service in cooperation with the District of Columbia Health Department has arranged to conduct chest x-ray examinations of large groups of government employees in Washington. Examinations of the employees of the government printing office were begun October 15. According to *Industrial Hygiene* arrangements have been made with Dr. Charles P. Waite, Washington, D. C., medical officer in charge of the government printing office to check the x-ray films of all workers showing signs of chest abnormalities. The examination of the government printing office employees will be followed by similar services in other war agencies.

Army Medical Service in the Middle East

After more than two years of war in the Middle East the work of the medical services of the British army can be pronounced good. The forces there operate in countries where malaria, yellow fever, typhoid and schistosomiasis are endemic. Yet the sickness rate has been kept low. The director of medical services has laid down that hospital beds must be provided in the ratio of 40 per thousand troops, but this incidence of casualties has never been attained. Comparison with the 1914-1918 war is most favorable. Then the armies in Egypt and Palestine averaged 170,000 and there were 500,000 admissions to the hospital for sickness. The corresponding figures for Iraq now are 300,000 and 60,000.

Effective prophylaxis and improved hygiene have rendered almost negligible the diseases which in the past proved most crippling to our armies. Typhoid has been mainly restricted to prisoners of war, and last year there were only 183 cases among our troops. Typhus has been confined to the Poles evacuated from Russia and it almost disappeared under disinfection and regular bathing. Tetanus has been practically nonexistent. Malaria, which was a scourge in the Balkan campaign of the last war, has been kept down by reconnoitering places unsuitable for camp sites and marking them with notice boards. Heat stroke occurs mostly in Iraq and on the Persian Gulf and Red Sea. Not a single casualty from heat stroke or heat exhaustion has been reported from the tanks, in which it might be thought that intolerable temperatures would be reached in the African summer. The explanation seems to be that the aeration arising from the movement of the tank prevents the heat from becoming dangerous.

MOBILE CASUALTY CLEARING STATIONS

The new conditions of mechanical warfare in the vast spaces of the desert have produced revolutionary changes in the organization of the treatment of the wounded. Each unit has its own motor ambulances. Formerly the casualty clearing stations were stationary. Now they have to be mobile and are divided into light and heavy sections. Surgical service is carried as far forward into the fluctuating battle as possible. The units have worked with the battle eddying around them and bullets whistling through the operating tents. Some were captured by the enemy and recaptured in a few days.

These mobile units have been the means of saving hundreds of lives, for in abdominal and chest wounds and many head wounds the man can be saved only by surgical aid within an hour or so. Excellent results are reported from the sulfonamides, whether taken internally or poured into the wound. As an anesthetic in the mobile surgical units pentothal sodium has proved invaluable. Burns and desert sores are treated with methylrosaniline jelly, which is held to surpass all previous remedies for the purpose.

AIR AMBULANCES

The long lines of communication in the desert have caused much suffering to the wounded, who sometimes have had to be jolted for hundreds of miles. Evacuation by air is an obvious alternative. The Australians had a few ambulance planes but the British medical corps had none, so they had to use ordinary transport planes. There was difficulty in

removing wounded from the forward areas, as the same landing grounds had to be used as for the fighting planes. If painted white, like hospital ships, they draw attention to the landing ground if they have no distinguishing marks they are exposed to the risks of fighting aircraft.

DEVELOPMENT OF SPECIALIZATION

A degree of specialization comparable with that of civilian hospitals has been developed. Face wounds are handled at a special maxillofacial center. There are separate centers of physical therapy and massage and for the treatment of psychoneuroses, head injuries and orthopedic and chest cases. There are mobile dental and ophthalmic units, which have done valuable work.

THE POLYGLOT PROBLEM

An extraordinary number of races and languages are represented in the Middle East command. Each has its own standards and requires, as far as possible, to be attended in its own hospital and by a medical staff which speaks its language. There are labor units recruited locally—Palestinians, Syrians, Iraqis and Persians—and others from remote colonies of the empire, such as Mauritius and the Seychelles. There are thousands of African Negroes. Among the troops are Indians (both Moslem and Hindu) and our allies—Poles, French, Greeks, Czechs. All have to be provided for separately. No wonder that there are seventy-five general hospitals. The supply of drugs and equipment has been well maintained.

The Army School of Occupational Therapy

The profound disturbance of our national life produced by the war has brought some benefits, though small compared with the injuries. In the last war the value of occupational therapy was recognized, but afterward it flourished more in the United States and Canada than in this country, and when the British Association of Occupational Therapists was formed in 1936 emphasis was laid on the benefit of the treatment in mental rather than in physical cases. This war has again drawn attention to its value. There is a flourishing army school of occupational therapy which has recently taken in a second batch of pupils, having sent its first batch, mainly masseurs enlisted in the army medical corps, to treat the sick and wounded at home and overseas. This second group consists of twenty-six girls, who are skilled masseuses but who are learning how to blend their professional skill with the teaching of useful crafts and occupations for the benefit of temporarily disabled soldiers.

At present all the patients at the school are from units serving at home. Crafts are taught to engender the creative spirit while remedying physical disability. Fretwork is done on a bicycle driven machine which helps an injured knee, shaping and polishing buckles, on a treadle sandpapering machine for injured ankles. Games, such as table tennis and darts, are played for leg and arm exercise and drafts are played on the floor with the feet for reeducation after leg injuries. Men are encouraged to use their initiative in the handicrafts, and some remarkably fine work has been done.

Shortage of Practicing Midwives

There is a shortage of practicing midwives which is due not to any diminution of women seeking training as midwives or of those already qualified but to the fact that only a proportion of qualified midwives engage in practice. The remainder engage in other nursing. They have qualified as midwives because this is considered a recommendation by the public bodies who make nursing appointments. The roll of midwives for England and Wales contains sixty-five thousand names, which is more than sufficient, and yet there is a shortage of midwives in practice.

BRAZIL

Sept 22, 1942

The Eleventh Pan American Sanitary Conference

The eleventh Pan American Sanitary Conference was held in Rio de Janeiro, September 7-18, under the chairmanship of Dr J de Barros Barreto, director of the National Department of Health of Brazil. The program included the subjects continental defense and public health, survey on chest conditions tuberculosis and pneumoconioses, influenza, undulant fever, typhus fever, American trypanosomiasis and other parasitic diseases, diarrheas and salmonellosis, degenerative diseases, including cancer and those of the cardiovascular system, sanitary engineering, malaria, nutrition, fundamental rules of health project of a standard sanitary code for the Americas. Almost all the American republics were represented at the conference by their most prominent health officers. The delegation of the United States consisted of Dr Thomas Parran, Surgeon General U S Public Health Service, and Dr G L Dunnahoo of the same service, Dr W H Sebrell of the National Institute of Health, Dr George C Dunham U S Army, Dr Charles S Stephenson, U S Navy, Dr Forest Linder of the Bureau of the Census, Dr Abel Wolman of the Johns Hopkins University School of Medicine, Dr Fred L Soper of the International Health Board of the Rockefeller Foundation, Drs Hugh S Cumming, John D Long and Aristides A Moll of the Pan American Sanitary Bureau. The delegation of Brazil included Drs J de Barros Barreto, Almir Castro, Mario Pinotti, Humberto Pascale, Alberto Amarante, Jansen de Mello and Carlos Chagas Jr, all of the National Department of Health. The other delegates were Drs Rodolfo Vaccarezza, Jorge Claypaul and Francisco Martinez of Argentina, Drs Abelardo Benavente and Alberto Ibañez of Bolivia, Drs Julio Caballero, Eugenio Suarez, Benjamin Viel, Mario Prado, Hernando Urzua, Henrique Laval, Victor Grossi de la Guardia and J Binimells Roa of Chile, Dr Augusto Fernandez of Colombia, Dr Solon Nuñez of Costa Rica, Dr Manuel Robiou of the Dominican Republic, Drs L Isquieta, Perez Lewis, W Hackett and Attilio Macchiavello of Ecuador, Drs Manoel Arroyo and Carlos Vassaux of Guatemala, Dr Jules Dhebaud of Haiti, Dr Pedro Ordoñez Diaz of Honduras, Drs Martinez Baez and Alberto Leon of Mexico, Dr Honorio Arguillot of Nicaragua, Drs Guilherme G Paredes and Carlos Guardia of Panama, Drs Ramon Prieto, Miguel Oliveira e Silva, Leandro Pereira, Raul Peña, Jorge Roig, Manuel Ochoa and C M Ramellia of Paraguay, Drs H Paz Soldan, Cesar Suleta, Carlos La Puente, Hugo Pace and Hugo Pesce of Peru, Drs F S Osegueda and Victor Sutter of Salvador, Drs Henrique Clavaux and Estenio Ormaeche of Uruguay, and Drs Rafael Iribarren and Arnoldo Gabaldon of Venezuela. Canada was represented by her minister to Rio de Janeiro, Mr Jean Desi, and the International Bureau of Labor of the League of Nations by Dr R Paula Lopes, a Brazilian specialist who came from Canada for the conference.

The most important subject of the program was continental defense and public health, which had been scheduled to be reported by a representative of Cuba, who could not be present or send the report. A committee was appointed by the conference to study this important subject, and a report was read by Dr Parran, who was the head of the committee. In the report Dr Parran said that in the present war public health takes on a new urgency, and, instead of caring primarily for the health of the individual, we must now attain it for the nation's security. He transmitted to the representatives of the other American nations the interest and the willingness of the United States government to support any reasonable proposal designed to facilitate the integration of continental activities within the limits imposed by military exigencies. Dr Parran's report attempted to summarize into a few items

the more important impacts of war on civilian health problems. To begin with there are the great movements of population that occur in wartime, the shifts in industry, the construction of cantonments and munition plants, and new mining activities, as well as the threat of enemy action, which may cause wholesale evacuation, creating urgent problems of sanitation, malaria control and increase in venereal disease. Shortage of health and medical supplies develop because overseas sources are disrupted, and basic materials are needed for military purposes. Industrial health protection becomes more complicated by the sheer increase in the number of industrial employees, by the longer hours of work, by the increase in accidents and by the rise in occupational diseases. Scarcity of foods is traditionally a part of war, among other reasons because of transportation difficulties. The health authorities must guide the rationing systems to insure minimum nutrition standards. Quarantine problems increase, epidemic intelligence breaks down and sanitary safeguards are weakened by military exigencies. The great speed of planes threatens greatly to spread exotic diseases and their insect vectors. In summary, said Dr Parran, 'This war will bring new and difficult tasks to the health forces of each nation. There will be no more health business as usual until the war is won. In this total war, total strength and fitness and health are essential to total victory.'

The conference approved the resolution here summarized. Whereas the further extension of the hostilities throughout the world has demonstrated the importance of public health problems, whereas the threat of the extension of the hostilities to the western hemisphere requires the intensification of the preparation for the defense in the field of public health, whereas the equality of sacrifices for the common defense of the western hemisphere in the field of public health is a recognized principle, the eleventh Pan American Sanitary Conference resolves to recommend the governments of the American republics (1) to adopt measures to conserve and improve the medical and other supplies necessary to the preservation of the public health and the continental security and to promote the interchange of these supplies with the aim of satisfying the continental necessities in the matter of health, (2) to make, in each nation a survey of the geographic distribution of the transmissible diseases of importance in wartime, in accordance with a plan suggested by the Pan American Sanitary Bureau, (3) to collect without delay, epidemiologic and health data, to be sent to the bureau in order that it may be able to distribute all these informations to the American republics, (4) to make an inventory of the available stock of the supplies essential to the maintenance of health in order to secure the possible and convenient utilization of the surpluses for the cause of continental defense, (5) to make a survey of the most important medical and sanitary necessities in order to enable the several republics to help one another, (6) to prepare a confidential report on the results of the aforesaid surveys which, within the limits of military exigencies, shall be submitted to the appreciation of the Pan American Sanitary Bureau and the interested nations, (7) to utilize fully the cooperation of the Pan American Bureau in all the activities related to the problems of health and sanitary defense and in the execution of the surveys mentioned, (8) to request, under the auspices of the Pan American Bureau, the help of the neighbor nations in case of epidemics threatening the health of the populations of the other republics and the continental security, and (9) to adopt the most drastic measures to control the danger of the spread of transmissible diseases, through the civil and military air transportation of patients, germ carriers and animal vectors, as this possibility is now greatly increased as the result of the extension of speedy air transportation via unforeseen routes. In this case it is suggested that the help of the other nations be requested, and the Pan American Sanitary Bureau will function as a clearing house for information and consultation.

Deaths

Walter Ralph Steiner * a specialist in internal medicine long a leader of medicine in Connecticut, died on November 4 in the Hartford Hospital, aged 71, of cerebral thrombosis. Dr Steiner was born in Frederick, Md. He received his master of arts degree at Yale University in 1895 then graduated at Johns Hopkins University School of Medicine Baltimore in 1898, serving as house medical officer at Johns Hopkins Hospital from 1898 to 1899. In 1900 he began the practice of medicine in Hartford, serving on the staff of the Hartford Hospital as pathologist and bacteriologist from 1901 to 1912 assistant visiting physician from 1905 to 1907 visiting physician from 1908 to 1937 and consulting pathologist and bacteriologist from 1912. He had been consulting physician since 1934 and chairman of the medical and surgical staff from 1925 to 1933. He had also been consulting physician to the Hartford Orphan Asylum, Bristol, New Britain General Meriden Middlesex (Middletown) and the Charlotte Hungerford hospitals, Torrington, and honorary physician to the Manchester Memorial Hospital.

In 1937 the Hartford Medical Society, which he served as librarian from 1903 to 1941 and president in 1929, named its library the Walter R Steiner Medical Library in his honor and in 1938 held special ceremonies to unveil his portrait, which had been presented to the society.

Dr Steiner had been secretary of the Connecticut State Medical Society from 1905 to 1912, chairman of its council from 1929 to 1933 and president from 1934 to 1935. He was president of the American Clinical and Climatological Association from 1934 to 1935, of the Medical Library Association from 1931 to 1933 and of the American Association of the History of Medicine from 1937 to 1939, member of the American Association of Pathologists and Bacteriologists and the Association of American Physicians, fellow of the American College of Physicians and from 1911 to 1932 secretary of the Congress of American Physicians and Surgeons. Except for a few sessions, Dr Steiner had been a member of the House of Delegates of the American Medical Association from 1919 to 1940. In 1931 he was given a degree of doctor of letters of humanity by Trinity College. Other groups in which he held membership included the New York Academy of Medicine, the Sons of the American Revolution, Society of Colonial Wars, the Maryland Virginia and Connecticut historical societies and various clubs.

Dr Steiner's death closes a useful career. He gave his time freely to the problems of organized medicine and counseled wisely in matters of its development. He made numerous contributions to the literature on internal medicine, pathology and medical history.

Horton Ryan Casparis * professor of pediatrics at Vanderbilt University School of Medicine and pediatrician in chief at Vanderbilt University Hospital, Nashville, Tenn. died of heart disease in his hotel room after attending a meeting of the Southern Medical Association in Richmond November 11 aged 51. Dr Casparis was born at Round Mountain Texas. He graduated at the University of Texas in 1915. He received his degree at the Johns Hopkins University School of Medicine Baltimore in 1919 and served an internship at the Willard Parker Hospital, New York. Later he was staff assistant at the Trudeau Sanatorium. He took postgraduate work at the Johns Hopkins Hospital and medical school until 1924 when he went abroad for a year to study in various European clinics.

Dr Casparis joined the faculty of Vanderbilt University School of Medicine in the department of pediatrics in 1925 and in 1928 he became professor. He was chairman of the

Section on Pediatrics of the American Medical Association from 1935 to 1936 and at one time held a similar position with the pediatric section of the Southern Medical Association. He was also a counselor of the latter. His affiliations included membership in the Davidson County Medical Society, the Tennessee State Medical Association, the American Pediatric Society, the American Academy of Pediatrics and the National Tuberculosis Association. He was a member of the liaison committee of the American Academy of Pediatrics and the National Tuberculosis Association and a director of the latter. At the time of his death he was a member of the committee on undergraduate medical education and a member of the council of the American Trudeau Society. He had been certified as a specialist by the American Board of Pediatrics and was a fellow of the American College of Physicians. He had also been chairman of the Advisory Committee on Maternal and Child Health Services of the U S Children's Bureau. Dr Casparis had served as president of the Southern Tuberculosis Conference and twice held the office with the Tennessee Tuberculosis Association. He was president of the American Board of Pediatrics and in October of this year had been chosen president of the Southern Trudeau Society.

A member of the editorial board of the *American Journal of Diseases of Children*, Dr Casparis had written numerous articles on tuberculosis in children, allergy and the various aspects of the mental health problem in children.

Henry Hall Forbes * New York, College of Physicians and Surgeons New York 1890 an Affiliate Fellow of the American Medical Association specialist certified by the American Board of Otolaryngology, a founder and early president of the New York Bronchoscopic Club was elected president of the American Bronchoscopic Society in 1934 member of the American Laryngological Association the American Laryngological Rhinological and Otolological Society and the American Broncho-Esophagological Association fellow of the American College of Surgeons formerly professor of laryngology at the New York Post Graduate Medical School veteran of the Spanish-American War served overseas as a captain in the medical corps of the U S Army during World War I major medical reserve corps consulting surgeon diseases of the nose and throat New York Post Graduate Medical School and Hospital.

consulting laryngologist, New York and Flower and Fifth Avenue hospitals, consulting otolaryngologist Lutheran Hospital New York, and Northern Westchester Hospital Mount Kisco bronchoscopist New York Foundling and New York City hospitals consulting bronchoscopist St Joseph's Hospital Paterson a trustee of the New York Dispensary and the Jenny Clarkson Home for Children a delegate to several international medical congresses aged 74 died October 25 of coronary thrombosis.

Charles Virgil Mosby * St Louis St Louis College of Physicians and Surgeons 1900 chairman of the board of directors of the publishing firm bearing his name since 1906 publisher of medical books and journals such as the *American Journal of Obstetrics and Gynecology*, *American Heart Journal*, *Journal of Thoracic Surgery*, *Journal of Laboratory and Clinical Medicine*, *American Journal of Orthodontics and Oral Surgery*, *American Journal of Syphilis Gonorrhea and Venereal Diseases*, the *Journal of Pediatrics Surgery* and the *Journal of Allergy*, author of "Making the Grade published in 1926 and Little Journeys to the Homes of Great Physicians William Beaumont—Physiologist Augustus Charles Bernays—Surgeon William McKim Marriott—Pediatrician," published in 1937 in 1938 was awarded the honorary doctor of science degree by the Bates College, Lewiston Maine aged 66, died, November 9 in the Grace Hospital Detroit of heart disease.

WALTER R. STEINER, M.D. 1870-1942

Frank Aloysius Roberts, Caldwell, N J, Medico Chirurgical College of Philadelphia, 1895, member of the Medical Society of New Jersey and the American Urological Association, veteran of the Spanish-American War, in 1914 served on the Mexican border and during World War I as a captain in the medical corps of the U S Army, at one time affiliated with the Newark City Hospital, the old German Hospital, now the Newark Memorial Hospital and the old New York Hospital, attending urologist at the Community Hospital, Montclair, and the Essex County Hospital, Cedar Grove, consultant to the Mountainside Hospital, Montclair, and St Mary's Hospital, Passaic, aged 67, died, October 17, of coronary occlusion.

Eric Liljencrantz Ⓢ Commander, M C, U S Naval Reserve, who had been called to active duty Nov 1 1940, was killed in an airplane accident while at sea near the U S Naval Air Station, Pensacola, Fla, November 5, aged 39.

Commander Liljencrantz was born in Oakland, Calif, Nov 6 1902 and graduated at Stanford University School of Medicine in 1929. On completion of his internship at the Highland-Alameda County Hospital, Oakland, he went abroad for a year to study radiology, first as voluntary assistant in the Surgical Clinic of the University of Kiel and later at the University of Berlin. For the year 1931-1932 he served at Stanford as assistant in medicine in the department of radiology. Since 1934 he had been assistant professor of medicine (radiology) at Stanford. In 1940 Commander Liljencrantz was granted leave of absence to fulfil his duties with the Bureau of Aeronautics in the Navy Department. He was consultant in neoplastic diseases to the Naval Hospital Mare Island, and the Marine Hospital San Francisco. Commander Liljencrantz was a specialist certified by the American Board of Radiology, Inc, and a diplomate of the National Board of Medical Examiners. He held membership in the American College of Radiology, the Aero Medical Association and the American Association of Industrial Physicians and Surgeons.

In 1937 Pan American Airways began to consult Commander Liljencrantz on personnel problems encountered in the Pacific Division and in 1938 he organized for them the medical services of this division. Acting as flight surgeon for the division, Commander Liljencrantz made flights to Hawaii, China and New Zealand and conducted research on problems of aviation medicine. On going into active service he directed his attention chiefly to problems of night vision publishing four reports on the subject. In 1941 he succeeded Capt John R Poppen as head of the Division of Aviation Medical Research of the Bureau of Medicine and Surgery and at the same time was appointed as official liaison officer from the Navy to the Committee on Aviation Medicine. In August 1942 the board of scientific advisers of the Institute of the Aeronautical Sciences appointed him director of the Aeromedical Research Laboratory, which the institute had expected to establish at the Guggenheim estate. Commander Liljencrantz had contributed to the literature on radiology and in 1939 was editor of the Cancer Handbook of the Tumor Clinic, Stanford University School of Medicine. In the field of aviation medicine he was a recognized leader. In time of war the loss of such men becomes of the greatest significance. Commander Liljencrantz by his qualities of leadership and by his character had earned the friendship and admiration of all who know him.

Benjamin Franklin Croutch Ⓢ Chicago, Loyola University School of Medicine, Chicago, 1918, fellow of the American College of Surgeons, associate in surgery at the University of Illinois College of Medicine from Nov 1, 1934 until Sept 1, 1940, member of the examining board of the U S Department

of Interior from 1925 to 1937 and member of the U S Veterans Bureau from 1937 to 1940, served in the medical corps, U S Army, during World War I, on the staffs of St Elizabeth's and the Illinois Central hospitals, aged 50, died, October 29.

Norvelle Wallace Sharpe, St Louis, Beaumont Hospital Medical College, St Louis, 1890, member of the Missouri State Medical Association, fellow of the American College of Surgeons, formerly vice president of St. Louis Medical Society, at one time on the staff of the U S Veterans Bureau, served during World War I, consulting surgeon City Sanitarium, City Isolation Hospital, City Infirmary, Home of the Friendless and the Chicago, Rock Island and Pacific Railway aged 73, died, October 24, of cerebral hemorrhage.

Herbert Dale Collins Ⓢ Oklahoma City, University of Oklahoma School of Medicine, Oklahoma City, 1926, specialist certified by the American Board of Surgery, fellow of the American College of Surgeons, past president of the Oklahoma City Clinical Society, associate in surgery at his alma mater, lieutenant colonel in the medical reserve corps of the U S Army, attending surgeon, State University and Crippled Children's Hospital and St Anthony's Hospital, aged 41, died, October 12, of generalized sepsis.

Hugh Watson Stephenson, Okmulgee, Ala, Medical College of Alabama, Mobile 1880, member of the Medical Association of the State of Alabama past president of the Walker County Medical Society, at one time a member of the state house of representatives, member of the medical reserve corps during World War I, in 1939 was awarded a plaque by the Walker County Medical Society commemorating his sixty years of active practice, aged 87, died, October 21, of chronic nephritis and arteriosclerosis.

Algernon Brashear Jackson, Washington D C, Jefferson Medical College of Philadelphia, 1901 formerly professor of bacteriology, public health and hygiene at the Howard University College of Medicine, fellow of the American College of Physicians, a founder and at one time surgeon in chief and superintendent of the Mercy Hospital Philadelphia, formerly assistant surgeon in the outpatient department at the Philadelphia Polyclinic, author of "Jim and Mr Eddy", aged 64, died, October 22.

Fred Valentine Hibbs, Carroll, Iowa, State University of Iowa College of Medicine, Iowa City, 1902 member of the Iowa State Medical Society, past president

of the Carroll County Medical Society veteran of the Spanish-American War, at one time mayor of Lohrville and a member of the town council, member and one of the founders of the Carroll Clinic, aged 68, formerly chief of the medical staff of St Anthony's Hospital, where he died, October 20.

David Thomas Jones Ⓢ Wausau, Wis, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1888, served on various advisory boards during World War I, chairman of the board of directors and chief of the staff of the Wausau Memorial Hospital for many years preceptor at the University of Wisconsin, Madison, aged 82, died, October 20.

Albert Leroy Reuss Ⓢ Belleville, Ill, Washington University School of Medicine, St Louis, 1903 at one time served as city health officer and as county physician, formerly secretary of the board of health of Belleville, formerly assistant chief surgeon of the Southern Railroad, on the staff of St Elizabeth's Hospital, aged 61, died, October 22, of coronary occlusion.

Julian Taylor Miller Ⓢ Medical Inspector, Commander, U S Navy, retired, Portsmouth, Va, University of Virginia Department of Medicine, Charlottesville, 1892, entered the

DIED WHILE IN MILITARY SERVICE

COMDR ERIC LILJENCRAINTZ, M C, U S N R
1902-1942

regular navy in 1907 and retired May 1, 1933 on his own application after thirty years' service, formerly director of public welfare in Portsmouth, aged 70, died, September 21

Elizabeth Carr Mallison, McKeesport, Pa., Woman's Medical College of Pennsylvania, Philadelphia, 1887, member of the Medical Society of the State of Pennsylvania, aged 77, on the staff of the Diamond (Pa.) Hospital, senior on the psychiatry staff of McKeesport Hospital, where she died, October 19, of cerebral hemorrhage and hypertension

F Edward Burke ☉ Wakefield, R I., College of Physicians and Surgeons, Baltimore, 1898, an Affiliate Fellow of the American Medical Association, past president of the Washington County Medical Society, for many years health officer of South Kingston and school physician of Narragansett, aged 77, died, October 21

John Denis Lucey ☉ Staten Island, N Y., Long Island College Hospital, Brooklyn, 1906, fellow of the American College of Surgeons, past president of the Richmond County Medical Society, for many years president of the board of directors and surgeon in chief at St Vincent's Hospital, aged 68, died, October 19

Emil Nicholas Kveton, Fort Wayne, Ind., Loyola University School of Medicine, Chicago, 1938, member of the Indiana State Medical Association, a lieutenant in the medical corps of the U S Naval Reserve, which he entered last January, aged 28, was killed in action at sea, August 9

Napoleon McDonald Burnett ☉ Lamar, Colo. Marion-Sims College of Medicine, St. Louis, 1899, member of the Colorado State Division of Public Health, at one time city and county health officer, aged 68, died, September 15, of tumor of the fifth cervical vertebra, probably metastatic from a carcinoma of the lung

Clarence C Del Marcelle, Green Bay, Wis., Marquette University School of Medicine, Milwaukee, 1914 served during World War I, aged 53, died October 11, of cerebral arteriosclerosis and a fracture of the vertebrae with severance of spinal cord as the result of an automobile accident seventeen years ago

Louis C Botkin, Ingram, Pa., Jefferson Medical College of Philadelphia 1881, member of the Medical Society of the State of Pennsylvania, past president of the Allegheny County Medical Society, for many years president of the Ingram borough council, aged 86, died October 23

Robert Milford Small, Auburn, Maine, Medical School of Maine, Portland, 1893 member of the consulting staff and at one time president of the staff at the Central Maine General Hospital, Lewiston, served as an Auburn councilman and as an alderman, aged 73, died, October 12

George Frank Brooks, Stillwater, Minn. University of Minnesota College of Medicine and Surgery, Minneapolis, 1900, member of the Minnesota State Medical Association, served during World War I, aged 64, died, October 7, at his home in Marine on St Croix

Samuel Glenn Major ☉ Pittsburgh, University of Pittsburgh School of Dentistry, 1921, Harvard Medical School, Boston, 1927, fellow of the American College of Surgeons, surgeon to the Western Pennsylvania Hospital aged 42, died suddenly, October 14

James Corbin Fvay, Atlanta, Ga., Atlanta Medical College, 1882, member of the Medical Association of Georgia, at one time coroner of Fulton County, aged 86, died, October 19, in the Grady Hospital of injuries received when struck by a trolley car

Frederick Bullwinkel ☉ Atlantic Highlands N J., Harvard Medical School, Boston, 1923, for many years served as school physician, on the staff of the Monmouth Memorial Hospital, Long Branch, aged 45, died, October 20, in Sea Island, Ga

Dorsey Funk Butterbaugh ☉ Elizabethtown, Pa., Hahnemann Medical College and Hospital of Philadelphia 1930, on

the staff of the Columbia (Pa.) Hospital, aged 40 died, September 23, in North Manchester of cerebral hemorrhage

William Henry Hope FitzGerald, New York University of Vermont College of Medicine Burlington, 1895, at one time on the staff of St Francis Hospital, Hartford, Conn., aged 70, died, October 21, in Stamford, Conn

Martin Eugene Drake, Newton Iowa, Western Reserve University Medical Department, Cleveland, 1885, Jefferson Medical College of Philadelphia, 1890 also a dentist and a pharmacist, aged 88, died October 23

Earl William McKelvey, Oscoda, Mich., Detroit College of Medicine and Surgery, 1924, served during World War I on the staff of the Mercy Hospital Bay City, aged 49, died, October 8, of heart disease

Estes Allen, Little Rock Ark. University of Arkansas School of Medicine, Little Rock, 1930, member of the Arkansas Medical Society served overseas during World War I, aged 53, died October 17

Charles Waldron Adams, Cambridge, Mass., Harvard Medical School, Boston, 1905, member of the Massachusetts Medical Society, on the staff of the Cambridge Hospital, aged 63, died, October 20

Louis L Burstien, Los Angeles, Drake University College of Medicine, Des Moines 1908, formerly associated with the U S Veterans Bureau served during World War I, aged 56 died October 15

THE PROFESSION AND NATIONAL LEADERSHIP

To the Editor—This war is showing us that we need one another desperately. New responsibilities are being forced on all of us. As never before we realize the necessity of pulling together to fight the common enemy. But we cannot blindly ignore the confusion and division that still exist in this country in the third year of war.

But it takes more than diagnosis to cure a fractured limb. It requires alignment of the fragments plus the healing forces inherent in a man's body. And to give this nation unity and an affirmative fighting philosophy requires more than emphatic words as to what is wrong.

I write primarily to comment on the communication appearing in *THE JOURNAL* on May 2 entitled "The Doctor's Part in Building Morale Seen as Step of Total Victory." I wish to bear out the practicality of the philosophy outlined. The writer said in effect that as doctors we can bring the answer to division and bitterness in the nation. The prescription is honest apology. Recently two friends of mine, one an industrialist, the other a labor leader, bitterly opposed me with me. I told them that I had no ax to grind but was concerned about the sabotaging effect that lack of teamwork was having on the war effort and that I had brought them together to see if broken relationships as well as broken bones could not be knit provided the jagged ends were brought into alignment. Incidentally I related how honest and costly apology had worked in my home and office.

The result was that these two men bridged their differences and decided to pull together for the sake of the war effort. The immediate result was to prevent three imminent strikes, one of which it was estimated would have cost the country \$100,000 a day. Their simple formula has been so effective that its spirit is taking hold in their industry right across the nation. I relate these facts to encourage the profession to use to the full the confidence people of all classes and stations in life put in us. For the fact that we are disinterested but not uninterested gives us as a profession tremendous leverage to bring the philosophy of teamwork to our communities and nation. Total war requires total effort by the total population. Here is an opportunity unmatched in history for the profession to provide the nation with leadership.

LOREN T. SWAIN, M.D. Boston

INTRAPERITONEAL ADMINISTRATION OF SULFANILAMIDE

To the Editor—I wish to call attention to an error contained in an editorial, "Intraperitoneal Administration of Sulfanilamide," in *THE JOURNAL*, July 4, page 796. The statement is made that "Jackson and Collier found in experiments on dogs that the concentration of the drug in the portal vein was forty times greater than in the jugular vein. There may be a special affinity of the liver for the drug." However, in the reference itself, "The Use of Sulfanilamide in the Peritoneum," by Howard C. Jackson and Frederick A. Collier (*THE JOURNAL*, January 17, p. 194) the statement is "Thirty minutes after the administration of the drug the difference between the sulfanilamide content of the portal vein blood and that of the peripheral blood was approximately 40 per cent of the peripheral blood level. At the end of four hours the concentrations were the same."

Obviously, the reference quotes the original paper inaccurately. Chart 9 in the original paper gives a level of 21 mg for the portal vein and 15 mg for the jugular vein concentrations at the end of one half hour in a 12 Kg dog.

This editorial has been quoted widely in support of the contention that hepatitis may be caused by a simple quantitative factor, i.e., high portal venous sulfanilamide concentration. But the only data presented are those of a single observation of a 21/15 ratio between the two circulations. Jackson and Collier themselves admit that the fact that "a large number of experiments was not carried out probably detracts from the accuracy of our figures."

My co-workers and I have performed experiments (to be published) on normal animals and have found that the systemic and portal venous concentrations of sulfonamides are the same during peritoneal absorption and therefore the drug level in the systemic circulation is a reliable index of the concentration in the portal vein.

POTASSIUM THIOCYANATE TREATMENT OF HYPERTENSION

To the Editor—In the article on fatal poisoning from potassium thiocyanate treatment of hypertension (Russell, W. O., and Stahl, W. C. *THE JOURNAL*, August 8, p. 1177) certain statements are made which are contrary to our conception of the method of control of thiocyanate medication. We are using thiocyanates almost exclusively in the treatment of essential hypertension with very encouraging results. So far we have encountered no serious toxic reactions; mild pruritic rashes are frequently encountered when the blood level approaches 15 mg per hundred cubic centimeters and can be controlled by careful control of the blood level; transient mild mental confusion is seen very frequently but so far has not been found troublesome. We give small doses (0.06 to 0.2 Gm daily) and make estimations of the blood thiocyanate level every two weeks at the onset of treatment and every two to three weeks until the level is stabilized within the therapeutic and below the toxic level and then every month. We attempt to establish a level of 8 to 12 mg, never permitting the level to exceed 15 mg.

Russell and Stahl state that their patient died while he was getting the "usually prescribed amount of the drug." Their protocol shows that he received 6 grams (0.4 Gm) daily for two weeks, with a blood level of 45 mg after one week and 152 mg after two weeks. In spite of the level of 152 mg the same dose which brought the blood level from presumably near 0 to 152 in two weeks was continued for five more days with symptoms of toxicity for the last two days. The blood level was not taken until three days after admission, when it was 217 mg. We consider a blood level of 15 mg as definitely the upper limit permitted and do not agree that 6 grams daily (after the attainment of that level by that dose in only two weeks) is the usually prescribed dose.

Nine cases of fatal thiocyanate poisoning are reviewed. In the 2 cases in which blood levels were determined they were found to be 187 and 217 mg, definitely above the safe levels of 8 to 14 mg (Barker, M. H. "The Blood Cyanates in the Treatment of Hypertension," *THE JOURNAL*, March 7, 1936, p. 762; Wald, M. H., Lindberg, H. A., and Barker, M. H. "The Toxic Manifestations of the Thiocyanates," *ibid.*, March 23, 1939, p. 1120). In 2 others strong traces "were found in various viscera." In 1 other from 97 to 18 mg was found in the tissues. Because potassium thiocyanate is distributed extracellularly (Wallace, G. B., and Brodie, B. B. "Distribu-

tion of Administered Iodide and Thiocyanate in Comparison with Chloride, and Their Relation to Body Fluids, *J Pharmacol & Exper Therap* 61 397 [Dec] 1937, Distribution of Administered Iodides and Thiocyanates in Comparison with Chloride in Pathological Tissues, and Their Relation to Body Fluids, *ibid* 61 412 [Dec] 1937) we assume that the blood levels were much higher than the tissue levels and probably in the toxic range. In the 6 cases in which thiocyanate was given therapeutically for the hypertension in all instances the patient received no more than the standard accepted therapeutic dose, yet two received 9 Gm in ten days, two 977 Gm in fifteen days, one 144 Gm in eighteen days and one (the author) 56 Gm in fourteen days. We never give more than 6 grams (0.4 Gm) daily and seldom give more than 3 grams (0.2 Gm). The doses in these fatal cases are far greater than are necessary or desirable.

The remarkable statement is made: "While the level of blood cyanate was studied in only 2 of the 6 cases treated for hypertension, essentially the same dosage was administered in the other 4 cases over comparable periods of time. Whereby it may be reasonably assumed that the blood cyanate values in those cases could not have exceeded significantly the levels in the cases in which the blood cyanates were determined."

As long as thiocyanate therapy is based on "reasonable assumptions" it will continue to be dangerous. Experience here and elsewhere shows that thiocyanate concentrations are notoriously variable and unpredictable. Dosage is not a reliable guide and blood determinations must be made at frequent intervals. Not only is thiocyanate retention an individual problem, but it varies greatly in the same individual from time to time (Goodman, Louis, and Gilman Alfred *The Pharmacological Basis of Therapeutics*, New York, Macmillan Company 1941, pp 573-574).

Further, Russell and Stahl state that renal damage increases the hazard because of uncertain and unpredictable excretion. It has been our observation that the blood level has little correlation with renal efficiency. In fact, we find that patients with severe impairment of renal function may require larger than average doses to maintain an average blood level.

Thiocyanates, when properly administered and controlled by continuous blood level determinations, offer considerable promise in the treatment of hypertension and are as safe as most other potent drugs. If not properly controlled they may be very dangerous.

"THE CHANGING CONCEPTS IN PATHOLOGY"

To the Editor—Reading your editorial "The Changing Concepts in Pathology," I thought the author might be interested in the definition of pathology current at Yale during my apprenticeship there: "Pathology is the study of the reaction of biologic systems to injury." This is a broad definition. Incidentally a friend, an economist once asked me how the demands of my specialty left any time for me to keep informed concerning his specialty. I replied that according to my definition of pathology it included a good deal of social sciences.

POLIOMYELITIS

To the Editor—Congratulations. The October 17 issue was one of the best issues of THE JOURNAL that it has been my pleasure to read. Since my training has been devoted primarily to physical medicine, I have long been interested in the problem of poliomyelitis.

To me the work of Dr. Sabin on the pathology of poliomyelitis presents a decided step forward. I have never been able to convince myself that the primary damage was the result of edema in the cord, regardless of how strongly others felt about it. I was glad to note that Dr. Sabin did not contradict the work of Hurst and that he found that 'neuronal damage was not due to edema and exudate of the inflammatory reaction'. This also offers a possible explanation of why fever therapy and the administration of concentrated salt solution does not relieve the condition through reabsorption of the edema.

The article by Dr. McCarroll appears to me to be the work of a man of narrow vision. In one respect however, the article may serve a very useful purpose. It may arouse and stimulate thought concerning Sister Kenny. She is being followed, almost blindly by the medical profession as well as the public. Any attack on her theories based on a sound foundation will serve to prevent undue deification by the public and blind obedience by the medical profession.

Dr. McCarroll's attacks on physical therapy demonstrate the narrowness of his vision by the limited way in which he has treated his patients. According to his observations untreated patients have far more chance of recovery than those who receive splints alone or who are splinted and treated with physical therapy. No mention is made of any patients treated without immobilization but with physical therapy. Therefore he cannot rightly conclude, as he has done, that 'it can be readily seen that no particular form of therapy provided results that were outstanding'.

Another fact which he ignores completely is that, regardless of the immobilization, physical therapy did produce a much higher percentage of normal, good and fairly well patients than those who received no physical therapy. I do not doubt that a physical therapist with foresight could have improved on these results.

His adherence to the old theory of subsidence of edema and how partial paralysis can "easily be explained on this basis" seems to indicate that he is looking for an easy "explanation" rather than the true facts regarding poliomyelitis.

Lastly, the fact that "physical therapy will never prove to be the answer to our problems in the disease" appears to be quite true. The "ounce of prevention" adage still holds good. But what is to become of those occasional cases which may still be encountered? For them, physical measures will always be an adjuvant and probably the treatment of choice in the rehabilitation of these unfortunate individuals.

Regardless of the final outcome of Sister Kenny and her methods, I feel that she has contributed greatly to our knowledge, if only for the reason that it has stimulated new thought. I myself believe that at this time her treatment offers the greatest hope for maximum recovery without deformity, that, regardless of the unfavorable reaction of physicians in England, she does offer an improved routine for treating the complications of poliomyelitis, but finally, I believe that eventually a modification of her method will be the answer to the physical treatment of the complications of poliomyelitis.

I hope that the possibility for controversy offered by Dr. McCarroll's article will bring forth some new food for thought on this important subject.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
Chicago Feb. 15-16, 1943. See Council on Medical Education and Hospitals Dr. H. G. Weiskotten, 535 North Dearborn Street, Chicago.

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in *The Journal* Nov. 14, page 861.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Oral Chicago Dec. 4-5. Sec. Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE Written Feb. 15. Final date for filing application is Jan. 1. Asst. Sec., Dr. William A. Werrell, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written Part I Various centers Feb. 13. Oral Part II May 1943. Sec. Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY Oral June. Sec. Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY Oral New York May or June. Final date for filing application is March 1. Sec. Dr. Dean M. Lierle, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PEDIATRICS Written Locally Feb. 12. Oral St. Louis March 27-28. Final date for filing application is Dec. 1. New York April 24-25. Final date for filing application is Jan. 1. Sec. Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY Detroit prior to the meeting of the American Psychiatric Association. Final date for filing application is March 1. Sec. Dr. Walter Freeman, 1028 Connecticut Ave., N. W., Washington, D. C.

AMERICAN BOARD OF UROLOGY Chicago Feb. 12-14. Sec. Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis.

North Dakota July Report

The North Dakota State Board of Medical Examiners reports the written examination for medical licensure held at Grand Forks, July 7-10, 1942. The examination covered 13 subjects and included 100 questions. An average of 75 per cent was required to pass. Two physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
University of Minnesota Medical School	(1936)		1
Temple University School of Medicine	(1941)		1
University of Manitoba Faculty of Medicine	(1941)		1
School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Loyola University School of Medicine	(1939)		Illinois
Northwestern University Medical School	(1935)		Illinois
School	LICENSED BY ENDORSEMENT	Year Grad	Reciprocity with
University of Minnesota Medical School	(1935), (1938)		

Maryland Reciprocity Report

The Board of Medical Examiners of Maryland reports 31 physicians licensed to practice medicine by reciprocity and 12 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners from Jan. 1 through Aug. 31, 1942. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
George Washington University School of Medicine	(1936)		Illinois
Emory University School of Medicine	(1939)		Georgia
Northwestern University Medical School	(1938)		W. Virginia
The School of Medicine of the Division of the Biological Sciences	(1937)		Illinois
Indiana University School of Medicine	(1938)		Indiana
State University of Iowa College of Medicine	(1925)		Kansas
University of Maryland School of Medicine and College of Physicians and Surgeons	(1937)		New York
Tufts College Medical School	(1911)		Maine
University of Nebraska College of Medicine	(1934)		Nebraska
Columbia University College of Physicians and Surgeons	(1901), (1923), (1936)		(1938) New York
Long Island College of Medicine	(1936)		New Jersey
New York University College of Medicine	(1935)		New York

Maine July Report

The State of Maine Board of Registration of Medicine reports the written examination for medical licensure held at Augusta, July 7-8, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-one candidates were examined, 18 of whom passed and 3 failed. Four physicians were licensed to practice medicine by reciprocity and 4 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Harrison Narcotic Act Conspiracy Between Physician and Company Selling Narcotics—The Harrison Narcotic Act provides that it shall be unlawful for any person to obtain by means of an official order form any of the drugs covered by the act for any purpose other than the use, sale or distribution thereof in the conduct of a lawful business in such drugs or in the legitimate practice of his profession. The defendants Direct Sales Co., Inc., Dr. John Victor Tate, and certain others who pleaded guilty, were charged with a conspiracy to violate this proscription and were found guilty by a jury. Thereafter the defendants moved for a new trial and for arrest of judgment which came on for hearing before the U. S. district court, western division, South Carolina.

The evidence showed that the Direct Sales Company solicited the business of Dr. Tate by means of catalogs and circulars sent to him every ten days. Narcotics were not listed in the catalog itself but the company inserted therein a sheet of paper approximately 4 inches wide by 5½ inches long, sometimes colored pink and sometimes blue, on which was listed morphine sulfate. It offered tablets of morphine sulfate for sale in lots of 500, 1,000, and 5,000 ¼ and ½ grain (16 and 32 mg.) tablets, and the prices were from 30 to 40 per cent less than could be obtained elsewhere. The evidence showed that a narcotic agent of the bureau of narcotics visited the office of the company in 1936. He told the officers that it was his experience that when a physician ordered ½ grains of morphine sulfate it could be assumed that it was to be used for other than legitimate purposes. The average physician throughout the United States the agent further explained, would purchase from 200 to 400 ¼ grain tablets of morphine sulfate in one year. He showed to the officers a list of two hundred and four names of physicians who had been convicted of violations of the narcotic laws and, with the officers' permission, investigated the company's records. He discovered and so informed the company that fifty five of the two hundred and four physicians were its customers. He pointed out that the best known companies listed morphine in lots not to exceed 100 ¼ and ½ grain tablets, whereas the Direct Sales Company was listing it in lots of 500, 1,000 and 5,000. He asked the company to limit the amount to be sold on one order form to 1,000 ½ grain tablets to which it agreed. He testified that the president of the company told him that he had ordered 5,000 ounces of morphine in the year 1936. The evidence showed that the company did an annual gross business of from \$300,000 to \$350,000, and the government contended that its principal business was dealing in morphine. The United States commissioner of narcotics asked the company to discontinue the giving of discounts on narcotics so as further to reduce sales. The company complied with this request but immediately listed prices with the discount already figured off.

Dr. Tate, according to the evidence, had been sending in order forms for morphine sulfate on an average every five days. All orders were for 1,000 ½ grain tablets, with the exception of one submitted on June 28, 1939, in which he ordered 1,000 ½ grain tablets and 100 ¼ grain tablets. On that occasion the company filled his order for the 1,000 ½ grain tablets and wrote a letter to him requesting that he submit another order form for the remainder. It was contended by the government that this letter, while informing the physician of the rule that only 1,000 tablets could be ordered on one order form, suggested to him that all he needed to do was to split his purchase up into different order forms. This letter was so understood by Tate, it was argued, as shown by the fact that during the succeeding thirty days he ordered 6,000 ½ grain tablets, or 1,000 more than in any other thirty day period. These orders came with regularity, on many occasions one shipment was in the mail to Dr. Tate while his order form for another lot was on the way to the company. With negligible exceptions, Dr. Tate ordered no other preparations and he ordered no codeine.

Expert witnesses for the government testified that the standard dose of morphine was from ⅛ grain (8 mg.) to ¼ grain, and in rare instances ½ grain. The court said that the company was bound to know that the volume of morphine being purchased by Dr. Tate could not by any stretch of the imagination be dispensed by him in the course of the legitimate practice of medicine and must therefore have known that he was diverting it into unlawful channels, particularly after it had been informed that 26 96 per cent of all physicians in the United States convicted of violations of narcotic laws were its customers. The company contended that because it did not know Dr. Tate or any of the other defendants it could not conspire with them. Its dealings with the physician, the court pointed out, were over a period of years. It knew that he could not lawfully dispense the amount of morphine he was purchasing. These facts were sufficient to justify the jury in concluding that the company with this knowledge, was combining with others to dispose of the drugs unlawfully. The company from time to time changed the form of its advertisements of narcotics so as to keep continuously before the physician attractive prices for large lots. It was as though, the court said, the company's own salesman every ten days came around and personally solicited using the arguments set forth in the advertisements, all the while knowing the impossibility of the drugs being used lawfully and that if they were used unlawfully other persons were associated with the physician in such use. Knowing this, the company solicited encouraged, instigated, induced, counseled and aided Dr. Tate and his associates. The decision does not describe in detail the manner in which the physician disposed of the narcotics although one of the defendants who admitted guilt testified that "one of the purchases" he made from Dr. Tate was in a bottle of the defendant company.

In the opinion of the court, the evidence was sufficient to justify the verdict of guilty, and the defendants' motions for a new trial and for arrest of judgment were denied.—*United States v. Direct Sales Co., Inc.*, 44 F. Supp. 623 (1942)

Drugs Patentability of Drug Used to Relieve the Pain of Cancer—The petitioner, the Canadian-American Pharmaceutical Company, commenced an action against the Commissioner of Patents to obtain a patent on ensol, a drug for reducing the pain of cancer, and on processes for its manufacture. The district court dismissed the complaint on the ground that the drug was not sufficiently reliable, useful and important to warrant the grant of a patent. The petitioner then appealed to the United States Court of Appeals for the District of Columbia.

The physician who originated ensol, Dr. Hendry C. Connell testified that he had supervised its use in 800 to 1,000 cases of painful cancer and that in 90 per cent of those cases pain was reduced and less sedative was required. Pain was also reduced, according to the evidence, in 279 of 289 cases of painful cancer which were studied by his father, a former dean of the Medical Faculty of Queen's University, and in many of those cases relief was immediate and complete. Another physician testified that he had treated 18 cancer patients with ensol that pain was "definitely a symptom" in 14 and that the pain was reduced in 12. More than one thousand physicians, it was shown have administered the drug in cases of cancer, and their "almost unanimous opinion" was said to be that it relieved pain. Two independent physicians investigated ensol for the Ontario government and they testified that it reduces the pain of cancer in the great majority of cases. The Ontario government's Commission for the Investigation of Cancer Remedies reported that "In the great majority of cases treated there appears to be relief of pain."

It seems clear from the evidence of case histories, physicians' reports and the examination of patients that Ensol used according to directions, is harmless and that it produces no undesirable immediate or remote effects. Improvement is manifested by lessening of pain and tension. There was evidence, however, that ensol often caused "transient pain."

The Commissioner of Patents, in justifying a denial of the patent, relied on a series of experiments which indicated that ensol did not check the growth of cancer tumors in mice and rabbits. This evidence, the court said, did not throw any sub-

stantial doubt on the proposition that the drug usually reduces the pain of cancer in man. It may be, said the court, that some medical scientists would discourage the use of enso pending further tests. Whether its use should be encouraged or discouraged however was not for the court to decide. The issue was whether enso under the evidence in the record had been clearly shown to have utility within the meaning of the patent law. On all the evidence the court held that it was clear that enso does, in many cases, reduce the pain of cancer and that it causes no serious harm. The judgment denying a patent was therefore reversed.—*Canadian-American Pharmaceutical Co v Col*, 126 F (2d) 847 (1942)

Malpractice Liability of Surgeon for Negligence of Anesthetist—The plaintiff engaged the defendant surgeon to perform a major abdominal operation, and arrangements were made for another physician, also a defendant in this case, to administer a spinal anesthetic. In attempting to administer the anesthetic the anesthetist broke the needle, a piece about 2½ inches long (64 cm) remaining embedded in the plaintiff's back. On being informed of the accident the surgeon secured another needle administered the anesthetic and completed the operation. Some nine days later after the plaintiff had recovered sufficiently from the abdominal operation, the defendant surgeon removed the broken needle. Subsequently the plaintiff commenced an action for malpractice against the defendant surgeon and the defendant anesthetist. At the conclusion of the plaintiff's evidence the trial court sustained a motion for a directed verdict in favor of each of the defendant physicians and the plaintiff appealed to the court of appeals of Ohio Summit County.

The evidence established the fact that if a needle used to administer a spinal anesthetic is properly inserted it can with little force be thrust through soft tissues to its proper destination. The needle in the present case however had contacted the bony part of the spine and had not followed a course through soft tissue. The court was of the opinion that while the breaking of the needle did not permit the application of the rule of evidence known as *res ipsa loquitur* nevertheless the breaking of the needle under the circumstances coupled with its location outside of the channel of soft tissues and against the bone, established a *prima facie* case of negligence sufficient to necessitate an explanation from the anesthetist.

Concerning the liability of the defendant surgeon however, the court held that the evidence did not establish a *prima facie* case of negligence. In reaching this conclusion the court said that it was mindful of authorities which hold that when one physician, acting in concert with another in the performance of an operation perpetrates an act of malpractice the other may be held liable for the acts of the tortfeasor if he observes such tortious conduct and lets it continue without objection, or if he fails to observe and act on that which, in the exercise of ordinary care and diligence under the circumstances, he should have observed and acted on. The defendant surgeon and the plaintiff entered originally into a consensual contract. At the time the parties understood that the defendant surgeon was not to administer the anesthetic but was only to perform the operation. The surgeon suggested that the anesthetist be engaged and no objection to this was interposed by the plaintiff, and the latter accepted the services of the anesthetist. Although the defendant surgeon actually engaged the anesthetist, nevertheless a separate contract was thus created between the plaintiff and the anesthetist by implication. Under these circumstances each physician was engaged to perform a separate and distinct work independent of the other. The trial court did not err, therefore in directing a verdict in favor of the surgeon.

The judgment in favor of the defendant anesthetist was reversed.—*Wiley v Wharton*, 41 N E (2d) 255 (Ohio 1941)

Malpractice Tetanus Following Failure to Sterilize Wound—The plaintiff's son a boy aged 10 years, sustained a crushing injury to the middle finger. The defendant physician who was called to treat the injury arrived about half an hour later and found that considerable blood had clotted about the finger. Without any cleansing or preparation, he lifted the nail slightly and squeezed tincture of mercuric iodine underneath it packed the finger in metacemic jelly (5 per cent tannic acid,

4 per cent benzyl alcohol and metaphen 1 5,000 in a water soluble base) and bandaged it. This treatment was continued for several days until the patient showed symptoms of tetanus. The patient was taken to a hospital where another physician administered tetanus antitoxin, but death resulted from tetanus the following day. In a subsequent suit for damages against the defendant physician, the jury found for the defendant. The trial court granted a new trial and the defendant appealed to the district court of appeal, first district, division 1, California.

It is well settled, said the court, that in undertaking the treatment of a patient a physician impliedly contracts and represents not only that he possesses the reasonable degree of skill and learning possessed by others of his profession in the locality but that he will use reasonable and ordinary care and skill in the application of such knowledge to accomplish the purpose for which he is employed. If injury is caused by a want of such skill or care on his part, he is liable for the consequences. The plaintiff in this case made no allegation that the defendant lacked the requisite skill and knowledge but contended that he failed to apply it. It was urged that there was no proper examination of the wound, no cleansing and no proper sterilization and that the application of the metacemic jelly operated to seal in any bacilli that were present and thus directly induced the fatal infection. A physician called by the plaintiff testified that under the circumstances of the case a use of reasonable medical care and skill by the attending physician demanded a thorough cleaning of the finger and that the finger should be given free access to the air to overcome any anaerobic tetanic germs. Other witnesses called by the defendant also stated that in the case of such a wound as was involved in this case ordinary care demanded a thorough cleansing and the application of an antiseptic. The court concluded that it was a reasonable inference to be drawn from the evidence that the infection would not have occurred if the wound had been properly cleansed and antiseptized.

An instruction to the jury to which the plaintiff objected, and which prompted the trial court to grant a new trial directed the jury to find for the defendant physician if it believed from the evidence that in deciding not to administer tetanus antitoxin he possessed and exercised the degree of skill, learning and care ordinarily possessed and exercised by physicians in the same line of practice in the same or similar localities. The vice in this instruction said the appellate court, is that it in effect told the jury to disregard all facts bearing on the defendant's failure to cleanse and sterilize the wound or any other act of negligence and to consider only the issue of failure to administer the tetanus antitoxin. This instruction, in the opinion of the court was prejudicially erroneous because it excluded an issue that was supported by evidence, and in giving it to the jury error was committed.

The order of the trial court granting a new trial was therefore affirmed.—*Pierce v Paterson* 123 P (2d) 544 (Calif 1942)

Accident Insurance Death from Pneumonia Following Operation—When an insured dies from pneumonia following a total hysterectomy the death does not, said the court of appeal of Louisiana, come within the provisions of an accident insurance policy which defines the term injury as 'bodily injury which is the sole cause of the loss and which is effected solely through accidental means while this policy is in force'.—*Waller v Continental Casualty Ins Co Inc* 7 So (2d) 383 (La 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints are a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Acidity of Ulcer Bearing Area in Duodenum—The acidity and the neutralizing ability of the contents of the first part of the duodenum in normal persons were determined by Berk and his co-workers by simultaneously aspirating material from the pars pylorica and the duodenal bulb at intervals of ten minutes with a specially constructed double lumen tube and a method that permitted more or less fluoroscopic control and proof of the position of the tube. Specimens were collected for half an hour before breakfast after a fast of twelve hours and for two hours after an Ewald meal. Twenty-three experiments were accepted as being technically satisfactory. These involved 2,225 separate determinations. The four readings made in the fasting state were averaged to give a single fasting value. The data show that the important "ulcer bearing" first part of the duodenum in normal persons is an acid area with an average pH in the fasting state of about 5.6 and after an Ewald meal of about 5. The duodenal bulb in normal subjects is endowed with a capacity to neutralize, buffer and dilute gastric chyme that generally exceeds the physiologic needs. Free acid is usually not present in the contents of the duodenal bulb in normal persons, if not absent its presence cannot be construed as an abnormal finding. The neutralizing ability of the contents of the first part of the duodenum is ineffective (pH 3.5 or less) in many normal subjects at some time after an Ewald meal. Usually the extent to which the neutralizing ability is overcome is not great, and the duration of its ineffectiveness is short. None of the customary measures of gastric acidity in normal persons can be used as a reliable index of the behavior of the corresponding effective acidity (pH) of the duodenal bulb contents. It is of physiologic interest that normal persons exhibit a neutralizing ability in the first part of the duodenum which is decidedly inferior to that of normal dogs, which are notoriously resistant to peptic ulceration and rarely, if ever, display a naturally occurring chronic duodenal ulcer. As the values for gastric acidity in dogs studied were distinctly greater than those of man, there is some support for the thought that perhaps the factors that cause chronic duodenal ulcer to develop in man be as much in deficient duodenal neutralization as in gastric hypersecretion, if not more.

- *Observations on Occurrence of Icterus in Brazil Following Vaccination Against Yellow Fever. J. P. Fox, C. Manso, H. A. Penna and M. Pura. Rio de Janeiro, Brazil —p 68

Icterus Following Yellow Fever Vaccination—The study by Fox and his associates was conducted with the support and under the auspices of the International Health Division of the Rockefeller Foundation and the Ministry of Health and Education of Brazil. The study is concerned with new major occurrences in Brazil of a serious disease associated with icterus which has followed vaccination against yellow fever. Although three separate vaccine lots have been clearly related to these occurrences, the participation of an additional factor not contained in the vaccines has been strongly suggested by otherwise unexplainable variations in the incidence of the disease among equivalently vaccinated groups. The available evidence as to the nature of both the vaccine born agent and the second factor does not permit the drawing of conclusions. Immunologic evidence exists for believing that the 17D virus itself was not related to the icterus. Some of the evidence, although far from conclusive, is compatible with the conclusions drawn by Findlay and his associates, namely that the responsible agent was a contaminating virus which gained entrance to the vaccine virus chain by way of human serum and persisted through an indefinite series of tissue-culture passages as a strain contaminant. The nature of the second factor is even more obscure, although the evidence is perhaps strongest that it is related to alimentation either on a deficiency or on a chronic intoxication basis. Clinical and pathologic findings have revealed a disease process which fundamentally involves injury to the hepatic parenchyma and which produces in fatal cases hepatic lesions similar to those seen in acute or subacute yellow atrophy. Although the disease is clinically indistinguishable from the group of cases classified as "catarrhal jaundice" or "infectious" or "epidemic hepatitis," it differs from the latter group in its unusually long incubation period and in its predilection for adults. Among the precautions adopted for the future production of vaccine the most important are the obtaining of an uncontaminated strain of 17D virus and the complete elimination of the use of human serum.

Pulse and Respiration During Labor in Women with Rheumatic Heart Disease—As in few normal pregnant women the pulse rate exceeded 110 and the respirations 24 in the first stage of labor, Mendelson and Pardee chose these rates

to determine whether in 200 women with rheumatic heart disease these rates differed in any way so as to give a warning of the approach of serious cardiac insufficiency. None of the women had medical complications apart from the cardiac condition, such as unexplained fever, thyroid disease or anemia. Only 1 woman was delivered by cesarean section, while 199 were delivered by the vaginal route. Intrapartum or postpartum cardiac failure occurred in 6, none of whom had ever previously been decompensated. The maternal mortality was zero. Elevation of the pulse rate above 110 and the respiratory rate above 24 or an elevation of the pulse rate alone during the first stage of labor preceded each instance of cardiac failure by sufficient time to afford a warning of its approach. Five of the 6 occurred among 10 patients with such elevations and 1 among 7 whose pulse rate only was elevated. Cardiac failure did not develop in any of the 12 patients whose respiratory rate only was elevated. Cardiac failure did not occur in patients with both pulse and respirations below these critical levels regardless of the severity of the cardiac condition. During the second stage of labor 75 per cent of the patients had both pulse and respirations above these critical levels, 65 per cent the pulse alone and 15 per cent the respirations alone. No serious significance could be attached to these rises unless they were preceded by similar rises during the first stage of labor. A similar percentage of normal women have shown these types of pulse and respiratory reaction during the second stage of labor. Proper management of the cardiac status may avoid severe cardiac failure even when the first stage of labor is unusually prolonged. The successful management of these patients during and after labor depends on careful antepartum care and cardiac functional evaluation, adequate antepartum digitalization and elimination of the second stage of labor in class 3 patients (New York Heart Association classification), and rapid adequate digitalization and elimination of the second stage of labor in any patient whose pulse and respiration exceed the levels considered as a warning of the approach of serious cardiac insufficiency.

Menadione for Prevention of Hemorrhage in New-born—A controlled study of menadione given during labor to prevent hemorrhage in newborn infants was instituted by Parks and Sweet in a group of indigent mothers. Patients admitted to the George Washington University obstetric service were given a single dose of 5 mg. of menadione by mouth immediately after admission to the ward, while those admitted to the Georgetown University service were used as controls. The infants of the treated mothers and of the controls were observed during their hospitalization for gross abnormal hemorrhage. Abnormal bleeding occurred in 22 of 1,594 infants whose mothers received no menadione and in 20 of 1,151 infants whose mothers did receive the vitamin. It was effective in raising the blood prothrombin levels of both the mothers and the infants. If an elevated blood prothrombin level is a significant factor in preventing neonatal hemorrhage, the authors are unable to explain the results of their survey.

Pregnandiol Determinations in Gynecology and Obstetrics—Hamblen and his co-workers tried to determine the clinical value of Venning's gravimetric method for determining urinary pregnandiol. To this end 7,114 twenty-four hour specimens of urine from 233 women were quantified for pregnandiol. A detailed summary of the pertinent data of 90 gynecologic and 12 obstetric patients is given. It was found that 21 of 49 patients whose episodes of bleeding occurred from progesterational endometrium excreted no pregnandiol and that 10 of 16 patients whose episodes of bleeding occurred from estrogenic bleeding excreted pregnandiol in amounts of the same order as those excreting it in association with progesterational bleeding. This obviously indicates that no reasonable prediction as to the nature of the endometrial response at the end of an ovarian cycle can be made from data on the urinary excretion of pregnandiol during that cycle. More consistent data were secured on 25 patients with no bleeding cycles, 7 with delayed menarche and 6 past the menopause excreted no pregnandiol, and 3 of 12 with intercurrent amenorrhea excreted pregnandiol. The clinical records of the last patients suggest the likelihood that they had cyclic ovarian functions. There were no consistent relationships between the curve of pregnandiol excretion and the

predicated luteal phase of the cycle or between the degree of progesterational proliferation of the endometrium and the amount of pregnandiol excreted. The data of the 12 obstetric patients were reasonably consistent. All excreted pregnandiol. The 4 patients whose pregnancies progressed to term despite a history of threatened or recurrent abortion excreted normal amounts of pregnandiol. In 7 of the 8 who aborted and miscarried the pregnandiol excretions were either initially and continuously low or became decreased with some daily values dropping to zero seven to ten days before the termination of pregnancy. Since these accidents occurred despite intensive progesterone therapy, the data on pregnandiol excretion were of no clinical value in gauging dosage levels. The authors conclude that Venning's method is unreliable as a diagnostic aid in gynecology and that the data it supplies permit of no effective therapeutic endeavors.

Urinary Infection in Pregnancy—Diddle and McKee report 4 instances of *Bacterium flexneri* as the causative organism in pyelitis or cystitis of pregnancy. Four similar cases have been described in the literature. The 4 present cases were encountered between January 1939 and March 1942 among 5,504 obstetric admissions. Seven of the total 8 patients showed the initial symptoms before parturition and 1 after, 2 had pyelonephritis, 2 cystitis and 4 pyelitis. Two patients had recurrences. The infection responded to the usual measures employed for cystitis or pyelitis. The incidence of 1 in 18 obstetric urinary tract infections attributed to the *Flexner* organism suggests that this infection is more common than generally believed. Previous gastrointestinal disease was not present. The organism may be confused with the paracol group, and differentiation and identification require thorough cultural and serologic study.

Epidemic Keratoconjunctivitis—Hogan and Crawford discuss the clinical aspects of the acute inflammatory eye disease that appeared around San Francisco in September 1941 and increased in number until January 1942, after which it decreased. They term the condition epidemic keratoconjunctivitis, as it describes an acute condition typified by edema of the lids and conjunctiva followed by intense hyperemia and little discharge. The keratotic spots 0.5 to 1.5 mm in diameter develop within five to eight days. They lie in the superficial substantia propria, beneath Bowman's membrane, and last for two months to two years. In all, the authors treated more than 200 patients, but they base their report on the 125 who were seen and examined throughout the course of the disease. The disease has been described as keratitis nummularis (Dimmer) and keratitis disciformis associated with superficial macular lesions. Its appearance and history suggest a relationship to Beal's form of conjunctivitis. The clinical picture varies greatly, even during epidemics, 75 per cent of the conjunctival infections are unilateral. Early the glassy edema of the conjunctiva is diagnostic, as are also involvement of the regional lymph apparatus, the lymphocytic type of conjunctival exudate, tiny petechial hemorrhages, pseudomembrane formation and the meager discharge. The severe conjunctivitis may or may not be followed by keratitis. It does occur in about 75 per cent, though this figure varies in different epidemics. At times keratitis may occur without a preceding history of conjunctivitis. The disease is

most likely caused by a virus, probably of the herpes facialis group. The disease is not highly infectious, it is transmitted by direct contact to susceptible persons, individual susceptibility varies, the disease is self limited and the ultimate prognosis of vision is good.

Goormaghtigh Cells in Human Kidney—Kaufmann studied the cell groups at the vascular pole of the glomerulus in 400 kidneys removed at operation or at necropsy from patients with and without hypertension. He found Goormaghtigh cells regularly at the vascular pole of the glomeruli situated in the outer part of the cortex. They appeared to be intrinsic parts of the human kidney and were situated close to the macula densa of the distal convoluted tubules. They also occurred in and along the wall of the afferent arteriole, the efferent arteriole, the interlobular artery and the terminal artery. Their location and cytologic characteristics suggest to the author that they are probably transformed smooth muscle cells of the vascular media. Although their close relationship to the macula densa suggests that they provide an opening and closing mechanism for blood flow to the glomerular tuft, his data and recent work on experimental hypertension of renal origin cast considerable doubt on this theory and strongly suggest the possible endocrine character of the Goormaghtigh cells.

Major Compound Fractures of Skull Vault.—Among 1,411 hospital admissions for head injuries Carmody found 42 with compound fractures of the skull vault. The method and extent of treatment depend on the degree of involvement. Fundamentally, the technic is total surgical debridement of the injured tissues. The decision as to when to operate is most important. After twenty-four hours, infection increases no matter how adequate the surgical procedure. These severely injured patients stand transportation much better preoperatively than postoperatively, especially when shock has been combated. Management consists of the preparatory, preoperative, operative and postoperative stages. If the distance to a properly equipped base or hospital is short the patient should be transported there immediately, but if it is great and his condition is such that the time spent in transit may be hazardous he should be brought to the nearest available point at which preliminary supportive procedures may be carried out and he can be prepared for surgical intervention. Patients with severe irreparable injuries will

usually have a progressively downward trend and will die within a few hours. If such a patient in a preliminary station has shown no improvement there is little point in removing him to a more fully equipped base. The exceptions are acute hematomas. The greater percentage of the nonoperative deaths occur within twelve hours. The preoperative phase, during which the patient's general condition has shown improvement, consists in the actual preparation for surgical intervention: removal of clothing, general examination and a comprehension of the patient's neurologic status. Tetanus antitoxin and chemotherapy should be given. A general anesthetic is avoided when ever possible and as most of the patients are unconscious, is not needed. When local anesthesia must be used, procaine hydrochloride is best especially for conscious patients who will cooperate. For mentally clouded patients when a general anesthetic must be used finally, drop ether is best and time is saved by using it from the beginning. The operative stage is governed by the extent, position and condition of the fracture. The author treated his patients without irrigating the wound. The wound is closed without drainage. The ears must be protected against the mastoid processes as compression from bandages against these bony prominences may cause sloughing of soft tissue. Supportive measures depend on the systemic need. The patient's postoperative course will depend on the prevention or control of immediate complications. Intracranial pressure is controlled by lumbar puncture, intravenous hypertonic solutions and fluids. Lateralizing signs warrant further intervention and good nursing care for restlessness. Chemotherapy should assume a supporting capacity to the surgical technique. An immediate continued postoperative rise in temperature is the gravest single prognostic sign. The first five postoperative days constitute the critical period, after which the prognosis for life is usually favorable. This considers only the effect of cerebral damage and not the development of some other complication. If convalescence was uneventful and unconsciousness no more than four days, most patients may be out of bed in two weeks. Before discharge, roentgenograms must be taken to determine whether all foreign material was removed and whether any later operation is indicated. Various types of fixed metal plates covering the bony defect have been recommended but best results follow direct bone grafting. In children regeneration may sometimes occur. A head support made of light plastic material to cover the involved area has been used with good results. Children should wear such a support for one year and if no regeneration occurs bone grafting should be contemplated. Other postoperative symptoms will depend on the neurologic status. Of the author's 42 patients 19 were not operated on, only 1 survived for three days and 1 for six days. There were 3 postoperative deaths among the 23 operated on. Of the 20 who survived, severe acute complications occurred in 3, 2 had hematomas and 1 an infection.

Acute Head Injuries—Glaser states that a classification based on the variations of intracranial pressure is of more value in the proper treatment and progress of patients with head injuries than classification based on skull fracture or pathologic considerations. Acute hemorrhage of sufficient magnitude to be fatal will always cause a high intracranial pressure sometime before death. The pressure if taken before the hemorrhage has become sufficient to increase it will naturally be low. If it is taken when the patient is at the point of death it may also be low. This does not apply to subacute and chronic subdural hematomas, in which instances the hemorrhage is actually slow enough to compress the brain without increasing the cerebral volume within the intracranial cavity. The intracranial pressure in such instances may be either high or low. If a high intracranial pressure is reduced following spinal drainage yet returns to higher limits on repeated taps, the diagnosis of hemorrhage is likely. Such changes in spinal pressure call for an exploration. If doubt exists, surgery is advisable. Lumbar puncture is without danger if the fluid is removed slowly and the original pressure is reduced only by half. It is invaluable for proper evaluation and interpretation. The localization of a hemorrhage by clinical signs alone is frequently impossible as it may be bilateral or combined with multiple cerebral damage. In such instances the pineal shift, the electroencephalograph, pneumoencephalogram or multiple burr openings are diagnostic aids. In acute cases the pneumoencephalogram is contra indicated.

Abdominal Muscular Rigidity—Yodice describes a maneuver which serves to establish the differential diagnosis between muscular contraction from peritoneal reactions and those from other causes. The patient is placed in the dorsal decubital position with the thighs abducted and flexed to 90 degrees and the feet resting on the bed or the examining table. The index and middle fingers are introduced into the rectum when with the left hand the abdomen is palpated at the site of the muscular contraction. If at the moment at which the anal sphincter is dilated the muscular contraction of the abdomen does not disappear, it denotes that the muscular contraction is due to peritoneal irritation (peritonitis), but if the contraction disappears it signifies that the contraction is due to pain of a colicky type for which an emergency surgical procedure is not required. The maneuver may be repeated and it establishes the differential diagnosis between muscular contraction of the abdomen due to peritoneal infection and a colicky type of pain contraction of nervous origin and of "phantom" tumor produced by contraction of the abdominal wall or intestine and of true tumor resulting from a neoplasm. When a phantom tumor is present the contraction disappears during the dilation of the anal sphincter. Valuable information is also obtained by test in cases of retroperitoneal tumor, aortitis or aneurysm of the abdominal aorta, which at times cause a muscular contraction of the abdominal wall. In aortic aneurysm the pulsation becomes less definite and the muscular contraction disappears at the moment the anal sphincter is dilated. The tumor diminishes in size.

Ultraviolet Blood Irradiation—During the last three years Miley has used ultraviolet to irradiate the blood of 151 consecutive unselected patients with acute pyogenic infection. The Knott technique, which withdraws, citrates, irradiates and returns it intravenously to the patient was employed. Most of the 151 patients received no chemotherapy before or after irradiation, a few were admittedly chemotherapeutic failures. The results show that 100 per cent of the patients with early lesions, 98 per cent with moderately advanced lesions and 42 per cent who were apparently moribund recovered. All the invading bacterial organisms disappeared except those in cases of *Staphylococcus aureus*, septicemia and acute or subacute bacterial endocarditis. The detoxification effect was most striking. Twelve to seventy-two hours following therapy nausea, vomiting, delirium, fever, general malaise, rapid pulse and rapid respiration subside. Abnormally high temperature falls by lysis or crisis. Grossly discernible peripheral vasodilatation occurred within five to ten minutes after the irradiated blood was returned to the venous circulation in more than 75 per cent of all patients. This persisted in some for more than thirty days. Ultraviolet irradiation of the blood can safely follow the administration of sulfonamide derivatives, quinine and iodides but sulfamidamide, sulfapyridine and iodides cannot be given within the first five days after irradiation without risking a probable photosensitive reaction. The convalescence of patients given only blood irradiation is much shorter than of those who also receive sulfonamides. Such irradiation increases the uptake of oxygen. General resistance is obviously increased. As yet in no instance of acute pyogenic infection uncomplicated by septicemia did the infection progress to septicemia after ultraviolet blood irradiation was employed.

Carbuncle of Kidney—Howard reports 3 cases of carbuncle of the kidney. The infecting organism was *Streptococcus aureus*, whose origin was some cutaneous lesion such as a boil or carbuncle. Its route of transference is undoubtedly the blood stream, that is, there must at least be a transient bacteremia. The primary lesion is undoubtedly an arterial or capillary embolus, following which in infarct forms, the fate of which will depend on its size, its situation relative to the kidney capsule and the reaction excited by it in the surrounding renal tissue. Spread by progressive venous thrombosis and production by the organism of a powerful necrotizing exotoxin in a subject of low resistance would produce a large necrotic area before localization would occur, and a few scattered areas of suppuration in the necrotic area would complete the picture of a classic carbuncle of the kidney. In a subject of greater resistance, spread from the primary embolus will be checked more rapidly and leukocytic activity will probably be greater. Liquefaction of the necrotic area will occur and a unilocular abscess of variable size by confluence of the suppurating areas may result. Multiple bacterial emboli in such a person will produce multiple cortical abscesses. A history of the primary focus is frequently obtainable. The first renal symptoms may occur from two days to many months later, the usual limits are two weeks to two months. The onset is generally sudden or ingravescent with sharp and stabbing pain in the loin (occasionally the abdomen) and rigor. Diagnosis involves a full consideration of the site of the lesion, the nature of the lesion and the extent of renal damage. Renal conditions to be excluded are 'primary bacillary pyelonephritis, pyonephrosis, infected hydronephrosis, renal tuberculosis and renal neoplasm. The mortality for the 84 cases reported in the literature (including the author's 3 cases) was 21 per cent. The factors which appear to influence the prognosis are age, sex and the state of the blood. The extremes of life, especially in males appear to be unfavorable periods. Of the patients who died as many as 5 had grossly defective hemoglobin values. Eminent pyemia naturally carries a grave prognosis, while involvement of both kidneys indicates a probable fatal termination. Nonoperative treatment has not been advocated, despite the possibility of spontaneous cure, and the author suggests that it is justifiable to temporize if the symptoms are mild in the hope of such an occurrence. In most cases surgical intervention will be necessary. In all smaller carbuncles the kidney should be saved if possible, while nephrectomy is indicated for large lesions. Gravely ill patients with a perinephric abscess should have the abscess drained at the primary operation, and when their general condition is improved the carbuncle should be attacked directly.

Enteritis Associated with *Giardia Lamblia*—An account of a protracted outbreak of enteritis due to *Giardia lamblia* affecting children and adults in an evacuee nursery home is reported by Ormiston and his associates. They believe the condition to be more common than is generally supposed. *G. lamblia* was found in 71 per cent of children and adults having loose stools at the time of examination and in only 32 per cent of those with normal stools. The organism was found in 82 per cent of children and adults with a history of intermittent or continual loose stools and in only 25 per cent of those without such a history. The infection was successfully cured in five days by atabrine dihydrochloride. The symptoms—chronic diarrhea and some anemia in the children and diarrhea with giddiness, loss of energy, anorexia, headache and epigastric discomfort in the adults—disappeared after treatment. The general nutrition of the children improved. Further observations are necessary to establish the exact degree of pathogenicity of *Giardia* for man.

Hemorrhagic Purpura in Exophthalmic Goiter—Bickel and Dicker describe two instances of hemorrhagic diathesis in patients with exophthalmic goiter. There were extensive involvement of the skin and mucous membranes and recurring visceral hemorrhages. This type of hemorrhagic diathesis is observed exclusively in the grave and acute forms of hyperthyroidism and is the result of multiple factors among which secondary hepatic insufficiency is the most important. Liver insufficiency presents an obstacle to the normal utilization of vitamin K by the liver and causes severe hemorrhages analogous to those observed in yellow atrophy of the liver and in certain forms of icterus and of hepatic cirrhosis. Treatment with vitamin K effects only a relative amelioration since there is not a real deficit but rather an impairment of its utilization by the damaged hepatic parenchyma. For this reason only the treatment of hyperthyroidism itself is likely to effect a cure of the hemorrhagic diathesis. It is probable that capillary fragility and vitamin C deficit frequently noted in these patients likewise play a part in the pathogenesis of certain simple purpuras in exophthalmic goiter, but these factors by themselves are incapable of causing the grave hemorrhagic diathesis in the pathogenesis of which hypoprothrombinemia is the essential factor.

 *Arteritis of Large Vessels as Sign of Infantile Congenital Syphilis C Torres Umaña and R Atalaya—p 253

Arteritis of Large Vessels in Children—Torres-Umaña and Atalaya observed 343 children with congenital syphilis from birth to 13 years of age. The group included children with a positive Wassermann or Kahn reaction or without a positive test but with syphilis of one or both parents. Arteritis of the aorta the pulmonary artery or of both, was demonstrated by physical and teleroentgenographic examination. The condition disappeared or improved with early antisyphilitic therapy. In several of the cases the condition was familial and was observed in two or three generations. The authors consider arteritis of the large vessels a sign of congenital syphilis. They advise antisyphilitic therapy even if the serologic tests are negative, provided one or both parents give a positive reaction.

Hypotension and Coronary Insufficiency—According to Ratschow and Eggers, angina pectoris is the result of coronary insufficiency, the pathogenesis of which has not been fully explained as yet. The impression has been gained that blood perfusion of coronary vessels is largely dependent on the factors that regulate blood pressure and that the mean aortic pressure

is by far the most important. If this is true, coronary insufficiency should be accompanied by deviations in blood pressure. The authors studied blood pressures in 46 verified cases of angina pectoris and found hypotension in nearly all of them. With reduction in the aortic pressure the blood perfusion of coronary vessels decreases. In dogs, mild deficiencies in aortic pressure involve the danger of ischemia. It is not a coronary spasm or a disproportion between dilatation of the coronary vessels and the peripheral combustion that produces myocardial ischemia but rather a deficiency in perfusion pressure. This suggests that it is not the man with hypertension who is likely to suffer from insufficiency of coronary blood perfusion but rather the person with hypotension. The authors found that stenocardia is much less frequent in hypertensive than in hypotensive patients. Schellong has demonstrated that even in hypertensive patients hypotonic regulatory disturbances are possible because perfusion disturbances may result from an inadequate blood supply even in the presence of high blood pressure. The authors believe that hypotension leads more frequently to coronary insufficiency than does hypertension. They therefore employed measures to increase the blood pressure.

Cholesterolemia and Atherosclerosis—Liebig made studies on 80 patients with atherosclerosis in order to throw light on the relations between cholesterolemia and atherosclerosis. He found the cholesterol content of the blood increased in 77 per cent of patients with aortic sclerosis, in 61 per cent of those with general atherosclerosis and in 87 per cent of those with nephrosclerosis, or in 75 per cent of all patients with atherosclerosis. Numerous pathologic anatomic observations and experimental research on atherosclerosis indicate the decisive importance of cholesterol for the pathogenesis of atherosclerosis. In essential hypertension the serum cholesterol content is increased in 77 per cent of the patients. The fact that the serum cholesterol content is increased in an equally high percentage of patients with atherosclerosis and with essential hypertension suggests not only that the etiologic importance of essential hypertension for the development of atherosclerosis is due to the increased load on the vascular system but that the accompanying hypercholesterolemia likewise plays an important part. The results of clinical studies and those of animal experiments speak against causal connections between blood pressure and serum cholesterol.

Anal Fistulas in Tuberculous Patients—Basanti and Sicuti noted anal fistulas in 48 of 732 tuberculous patients (65 per cent). Anal fistula was discovered in only 1 of 121 patients with extrapulmonary tuberculosis (0.82 per cent), the remaining 47 fistulas were found in 611 patients with pulmonary tuberculosis, an incidence of 7.7 per cent. Observation that anal fistula is more frequent in men was corroborated by finding it in 12 per cent of men and in only 1.6 per cent of the women. Patients with severe exudative and destructive pulmonary disease are more subject to anal fistulas than patients with the productive type of the disease. The perianal abscess either precedes or concurs with a progressive or regressive modification of the pulmonary process. Patients with severe tuberculosis may exhibit multiple anal fistulas surrounded by torpid granulation tissue, extensive zones of infiltration and detachment of skin at the external openings, whereas in the fibrous type of pulmonary tuberculosis the fistulas are benign. Specimens obtained by scraping the fistulous tract of 12 patients with ulcerative pulmonary tuberculosis yielded tubercle bacilli 8 times in the biologic test and 7 times by culture. In 15 patients with fibrous type of pulmonary tuberculosis and with negative sputum positive results were less frequent in material from fistula, 7 positive results were obtained with the biologic and 2 with the culture method. Tissues surrounding anal fistula were subjected to microscopic examination in 5 cases and in 3 tuberculous tissue was definitely demonstrated, in a fourth the tuberculous nature of the tissue was suspected and in the fifth the tissue was of nontuberculous character. The anatomic and clinical observations indicate that the perianal tuberculous abscess is probably of hematogenous origin.

Book Notices

The Pharmacopoeia of the United States of America (The United States Pharmacopoeia) Twelfth revision (U S P XII) By Authority of the United States Pharmacopoeial Convention Meeting at Washington D C May 14 and 15, 1940 Prepared by the Committee of Revision and published by the Board of Trustees Official from November 1 1912 Fabrikoid Price \$7.50 Pp 880 with illustrations Easton Pa Mack Printing Company, 1912

The twelfth revision of the U S P represents the passage of more than a hundred and twenty years since the first Pharmacopoeia of the United States was issued in 1820 with a preface which read in part "It is the object of a Pharmacopoeia to select from among substances which possess medicinal power those the utility of which is most fully understood and to form from these preparations and compositions in which their powers may be exerted to the greatest advantage. The value of a Pharmacopoeia depends on the fidelity with which it conforms to the best state of medical knowledge of the day." During this period there have been many changes, additions and deletions," but always with increasing recognition, national and international, until now the contents are revised every five years and the book is official in Costa Rica, Cuba, the Dominican Republic, Nicaragua, Panama, the Philippines and Puerto Rico as well as in the United States of America.

The twelfth revision contains one hundred and sixty new drugs and medicinal preparations, making a total of six hundred and fifty nine medicinal products. New U S P items include antimalarial drugs, antianemic preparations, diagnostic agents, heart medicaments, biologic products and closely related substances, surgical supplies, diuretics and related products, sulfonamides and other chemotherapeutic, antibacterial and antiparasitic agents, barbiturates and related drugs, antacids, hormones, ergot like products, antisiphilitic agents, narcotics, analgesics and anesthetics, vitamins, parasympathomimetic drugs, vehicles, preservatives and miscellaneous medicinals. Thus the contents of the book are U S Pharmacopoeial titles in English and Spanish, officers of the convention, the board of trustees, the general committee of revision, preface, the history of the United States Pharmacopoeia, articles of incorporation, constitution and by laws, abstract of the proceedings of the U S Pharmacopoeial Convention of 1940, international protocol, articles added to the U S P XII, articles added to the U S P XI by means of supplements, articles official in the U S P XI but not admitted to the U S P XII, changes in official Latin titles, changes in official English titles, general notices, monographs on vegetable and animal drugs, chemicals and preparations, general tests, processes and apparatus, reagents, test solutions, indicators, standard solutions and hydrogen ions, tables and index. To meet the needs of the medical profession, armed forces and other interested bodies there will be issued two types of "supplements", sheet supplements which will be issued whenever a need arises and a bound supplement which will appear midway between U S P XII and U S P XIII. Each purchaser of U S P XII is enabled to secure his copy of the bound supplement at no extra cost by using a mailing card which is pasted inside the back cover. These supplements will aid materially the up to date considerations of the revision committee.

The present revision is a commendable one and should be in every medical library and in any other library which relates to the testing or use of medicinal preparations. It is of value to the student, teacher and researcher, whether these individuals are in academic or commercial fields. Those who are familiar with the U S P need no introduction to the current edition, others, when they become acquainted with its contents, will not need a second introduction.

Text Book of Pathology By Sir Robert Muir M A M D Sc D Fifth edition. Cloth. Price \$10 Pp 991 with 599 illustrations Baltimore William Wood & Company 1941

The fifth edition of this textbook, written by the well known Scottish pathologist Sir Robert Muir, has been extensively revised since the preceding edition was published in 1936. The general plan is unchanged and about one fourth of the text is devoted to a discussion of general principles, while the remainder is assigned to the various fields of special pathology.

However, the author has made changes in all chapters, with deletions as well as additions of new material. He has also revised the order of presentation. Thus, in the first section, the topic of the retrogressive changes has been displaced from its initial position in favor of a discussion of circulatory disturbances. The first part contains especially good sections on the subjects of inflammation and repair, and on the general reactions of the body in infectious diseases. There is also considerable new material on neoplasms. The chapters devoted to systematic pathology are excellent because of a genuine effort to correlate morphologic and functional abnormalities. Illustrative material is abundant, with about six hundred black and white illustrations. Their quality is improved, perhaps because of a change in the type of paper. Altogether, this is a well proportioned and well synthesized presentation, admirably adapted for use as a student's textbook. The major limitation to its usefulness for the medical practitioner is the lack of a bibliography. The few references given, mostly in footnotes, are to standard text and reference books.

Non Pulmonary Tuberculosis By Michael C Wilkinson M B B S M R C S Medical Superintendent Essex County Hospital Black Notley With a foreword by Sir Henry Gauvain M D M Chir F R C S Cloth Price 12s 6d Pp 174 with 12 illustrations London Hamish Hamilton Medical Books 1942

This is a good contribution to the literature on tuberculosis as it occurs in other parts of the body than the lungs. In the fifteen chapters the author discusses pathogenesis and constitutional treatment of nonpulmonary tuberculosis, followed by diagnosis, treatment and prognosis of the disease as it attacks various lymph nodes, such as those of the cervical region, the abdomen and the chest. Tuberculosis of the bones and joints is presented in the following order: spine, hip, knee, ankle and foot, wrist, hand, elbow, shoulder and sacroiliac joints. One chapter is devoted to genitourinary tuberculosis, another to abdominal tuberculosis, another to the appendix, tuberculosis and pregnancy is discussed.

Dr Wilkinson reports largely on his own experience in the Essex County Hospital including the statistical material based on investigation and treatment of 593 patients during 1930 to 1937. He points out that the bovine type of tubercle bacillus is a common cause of tuberculosis of the cervical lymph nodes and summarizes the findings, in this respect, as being 90 per cent in Scotland, 65 per cent in England, 54 per cent in the United States and 25 per cent in Germany. Attention should be called to the fact that in the United States tuberculosis in cattle has been so much reduced in recent years that it has become a rarity for a child to be infected with the bovine type of tubercle bacillus. In England, he states that tubercle bacilli may be found in 5 to 10 per cent of the specimens of milk examined. The statement "children who suffer from tuberculous adenitis do not usually develop organic tuberculosis in later life" will be challenged by a number of tuberculosis workers, such as Miller, who says "One must remember that, while the tubercle in the lymph nodes in the neck may be conferring on the organism an added degree of resistance, they are at that same time harboring living bacilli which may be set free at any time to be carried to other parts of the body, there to grow in increased number. We must be guarded in accepting any such generalization as that tuberculous cervical adenitis may confer any practical immunity to tuberculosis elsewhere in the body. It will give rise to changed reaction and a heightened resistance, but this is probably of not enough actual potency to warrant our accepting it with complacency." While the author is of the opinion that children who become infected with the bovine type of tubercle bacillus may develop some immunity, he says "Deliberate immunization by that method must be condemned, however, owing to the disastrous effects which may follow bacillemic infection."

With reference to diagnosis, he says "A tuberculin test is most useful in the diagnosis. If it is negative the child can be regarded as nontuberculous. Many of these negative tuberculin children with dyspeptic symptoms are found to have septic tonsils, and it is possible that nonspecific ulceration in the ilium and secondary inflammatory changes in the glands may occur." Large numbers of clinicians will take exception to this statement with reference to tuberculosis of the tracheobronchial

glands "The diagnosis can be made with certainty by radio graphs in anteroposterior and lateral dimensions or by a tomograph", since the x-ray shadow is not pathognomonic shadows cast by various other diseases in the tracheobronchial lymph nodes have the same appearance as those produced by tuberculous lesions. Many will also question the statement that there is evidence to suggest also that the child who develops tuberculosis of the tracheobronchial glands is unlikely to develop pulmonary tuberculosis, since they consider that all cases of clinical pulmonary tuberculosis are preceded by primary tuberculosis, which often involves the tracheobronchial lymph nodes.

Dr. Wilkinson presents in a concise and splendid manner the various forms of extrapulmonary tuberculosis. His experience leads him to believe that pregnancy does not have a deleterious effect on these forms of the disease. This book should prove of great value to all physicians and, therefore, it is highly recommended.

Intestinal Obstructions. A Physiological and Clinical Consideration with Emphasis on Therapy Including Description of Operative Procedures. By Owen H. Waugensteen, B.A., M.D., Ph.D., Professor of Surgery of the University of Minnesota, Minneapolis. Second edition. Cloth. Price \$7. Pp. 434 with 143 illustrations. Springfield, Illinois & Baltimore, Charles C. Thomas, 1942.

The addition of continuous suction through an indwelling duodenal tube to the treatment of intestinal obstruction is undoubtedly one of the most important contributions to surgery in the past decade. For this and for clarification of the entire subject of intestinal obstruction we are indebted to Dr. Waugensteen. He has not only done a great deal of fundamental research but has popularized and taught the subject to the entire medical profession.

The first edition of this book was well written and carried a message which was well received and perhaps too well learned. Undoubtedly a few patients were treated conservatively who should have had early operations for relief of strangulation obstruction. The swing of the pendulum in that direction and the swing back away from too much conservatism was a natural sequence of events. In the second edition Dr. Waugensteen discusses this reaction and attempts to secure a more even balance between operative and nonoperative forms of treatment. More space is given to surgical technique especially newer forms of aseptic anastomoses. The use of nonsealing surgical procedures will undoubtedly further reduce the as yet too high mortality from intestinal obstructions.

The entire book has been rewritten, enlarged and brought up to date. Much fundamental experimental work is reported and the bibliography is complete. The illustrations, charts and tables are excellent and help to clarify a text which reads easily. This is a better rounded book than the first edition. More space is devoted to such related subjects as abdominal injuries, post-operative care and fluid balance. The special obstructions are considered in greater detail. It is a book from which every doctor can learn. It gives the best over all picture of intestinal obstruction available. The book is important to the research worker, the general practitioner and the surgeon.

Authority, Observation and Experiment in Medicine. By W. W. C. Topley, M.D., F.R.C.P., F.R.S., Professor of Bacteriology and Immunology in the University of London. Linares Lecture 1940. Paper. Price 40 cents. 1s. 6d. Pp. 46. New York: Macmillan Company; Cambridge University Press, 1940.

More than four hundred years have passed since Linares founded two lectureships, one in the University of Oxford and another at St. John's College in Cambridge. These lectures continue to be given year after year and many of the lecturers have been men of great note, as is W. W. C. Topley. Much thought went into the excellent writing of this essay. For instance, if a pioneer has no immediate followers, it is because his particular discovery has been made before its time. There has indeed been so thorough a fusion between medical science and medical practice over a large part of the common field that I do not think that any one would find it an easy matter to define clinical medicine as it exists today, except in terms of a professional activity. There is no way of gaining new knowledge so effective as controlled experiment, and no substitute for it. The really great scientist is

always a great artist. He observes things of which lesser men are blind, sees implications that other men ignore, forms hypotheses that look like guesses but have an uncanny way of proving true, and, when he goes wrong, learns more from his mistakes than others do from their successes.

Immunochemistry. By William C. Boyd et al. *Annals of the New York Academy of Sciences*, Volume XLIII, Art. 2, Pages 33-121, April 30, 1941. Paper. Price \$1.25. With illustrations. New York: The Academy, 1942.

This is a pamphlet bound in paper, consisting of a series of researches presented before the Conference on Immunochemistry, Section of Physics and Chemistry, New York Academy of Science, March 28 and 29, 1941. Among the topics treated are (i) an antigenic analysis of vaccinia virus (Smadel and Shedlovsky), (ii) isolation and purification of the M-substance of group A hemolytic streptococci (Zittle and Mudd), (iii) study of three chemically distinct components of serum complement (Ecker and Pillemer), (iv) mathematical relationships between antigen and antibody in the precipitin reaction (Kendall) and (v) the antigenic properties of hemocyanin (Hooker and Boyd). Each paper is clearly and concisely presented with an adequate bibliography, making possible a rapid orientation in several of the newer phases of immunochemistry. Clinicians should be particularly interested in Smadel's "duplex" (L-S) antigen in vaccinia virus and in the suggested practical applications of Ecker's "triune" complement.

Clinical Anesthesia. A Manual of Clinical Anesthesiology. By John S. Lundy, B.A., M.D., Head of Section on Anesthesia, Mayo Clinic, Rochester, Minn. Cloth. Price \$9. Pp. 771 with 267 illustrations. Philadelphia & London: W. B. Saunders Company, 1942.

This is an indispensable reference book for the shelves of hospital libraries or for physicians who may engage in the administration of general, regional or local anesthetics. It is essentially a report based on the extensive experience of the author. The average physician engaged in or supervising ordinary anesthetic procedures would be likely to select a group of relatively simple techniques for various types of anesthesia, however, and once this had been done would be unlikely to change the anesthetic method and agent at frequent intervals. It is for this reason that the reviewer feels that this book is more useful as a reference book than as a handbook which can serve as a simple guide. The latter information, which is based on the judgment and experience of the author, is available should the reader desire to develop it from the text or the tables.

Metodos modernos de amputação. Por Edmundo Vasconcelos, catedrático de clinica cirurgica, Faculdade de medicina da Universidade de São Paulo. Com a colaboração de Edmundo Pinto de Souza e Jose Gonçalves Filho. Paper. Pp. 253 with 258 illustrations. São Paulo: Companhia Editora Nacional, 1942.

Even though the text of this valuable and timely volume is in Portuguese, it will prove of inestimable value to every surgeon because of the unusually well executed pen drawings which illustrate the techniques involved in amputations. Chapter I deals with general methods, chapter II with general principles of amputations and chapter III with the indications for amputations. Chapter IV treats exhaustively of the technique of amputation and disarticulation of the upper extremity and chapter V gives the same complete consideration to the lower extremity. Chapter VII is a fine dissertation on prosthesis. The bibliography of four hundred and ninety-eight references is thorough and up to date. This timely and instructive volume is recommended unreservedly to students and surgeons.

Army Posts and Towns. The Baedeker of the Army. Compiled by Charles J. Sullivan. Fourth edition. Cloth. Price \$3. Pp. 199. Los Angeles: Haynes Corporation Publishers, 1942.

Just available is the latest edition of a book which has had extensive use by those who are in the Army. It is one of the most valuable compilations of important information. It includes not only a list of all army posts and towns but, under each, information concerning transportation to the area, the nearest town, a description of the available quarters, a statement as to whether or not you may have a private car, a point or two about schools, climate and clothing to be worn, also information regarding hotels, and additional remarks of value. Supplementary information includes the army corps areas, military insignia and decorations and the pay table.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LEAD PIPE FOR CONNECTION BETWEEN WATER MAIN AND RESIDENCE

To the Editor—I have been informed by my plumber that he is not permitted to install any other than a lead pipe from the water main into my house. The distance in my case is 75 feet and it would seem to me that there is a constant danger of lead poisoning if water used for drinking purposes is allowed to stand in this pipe. I have investigated the reason for this order and find that in the Chicago municipal code (chapter 83 paragraph 23) it is stated that only lead pipe can be used in such cases. I can see no difference in the danger between a lead pipe outside the house or inside the house. I know the latter is definitely avoided. I am informed that the city code dates back a good many years.

F. M. Whitsell, M.D. Chicago

[This inquiry was submitted to two authorities, whose respective replies follow.]

ANSWER—Lead pipe is used in the water supply of many cities and it causes no trouble, because the amount of lead which is absorbed by most waters is negligible. Lead piping is effective in forming an insoluble coating of salts which inhibits its solution. It is only when the water supply is acid, particularly because of organic acids, that it is a potential danger. It may also dissolve when different metals are used in the plumbing when galvanization may play a part. The question of whether serious amounts of lead are liberated may be solved by analyzing the water for its lead content. It is considered that 0.10 part per million is perfectly safe.

2. The practice of using lead pipe to connect water mains to the water lines within residences in the distribution of community water supplies is common and perhaps even general throughout the United States. It involves no significant risk to the users, since the volume of water involved is small in relation to the requirements of a household. The quantity of lead that is likely to be picked up by water in transit through a short section of lead pipe is small and it tends to decrease with time because of the gradual deposition of relatively insoluble material on the inside surface of the pipe. Water with highly solvent properties will dissolve some lead from such a pipe on standing. The length of standing and the temperature of the water will influence the final concentration, but the actual quantities of lead will be small. It is partly because of the hot water lines in the house, partly because of the greater surface of exposure and partly because of the longer period of stagnation of the water in certain parts of the system that the use of lead piping in the house is more dangerous than in the connecting line. Initially satisfactory water drawn from taps in established homes in American cities that employ lead connections between the mains and household lines rarely contains more than 0.02 mg per liter. The lead concentration in new homes or in homes with renewed plumbing is likely to be higher because of the plumbers practice (not universal) of luting the joints with lead-containing pastes. If it can be shown that the lead content of the water in any specific community is unduly high because of the solvent effects of the water on these connecting lengths of lead pipe, there is no doubt that other methods should be employed.

EARLY MOVEMENT AFTER HEMIPLEGIA

To the Editor—A patient aged 72 suddenly developed hemiplegia on the left side. The blood pressure was 180 systolic and 88 diastolic. The heart sounds were regular in rhythm and of good quality and there was no unconsciousness or any other psychic change. In accordance with Beckman's Treatment in General Practice, after the fourth day I advised passive movements of joints and encouraged the patient to begin active movements. Later in discussing the case with a colleague (not a consultant) he informed me that even on the tenth day passive or active movements are contraindicated in hemiplegia. I would appreciate your views.

M.D. Pennsylvania

ANSWER—The idea of early institution of both active and passive movement in hemiplegia is relatively recent but is now fairly well established. Nearly all the newer works agree with Beckman that much is to be gained and surely nothing lost if these measures are begun at the earliest possible time.

RESUSCITATION OF INFANTS

To the Editor—The mortality of newborn babies at our hospital and in our community is too high. We do not have an infant resuscitator at the hospital. As a member of the staff I would like to obtain from the proper committee of the American Medical Association literature and statistics on the benefits of an infant resuscitator in a community hospital. Can you recommend any special type of resuscitator?

M.D., Vermont

[This query was referred to Dr. Herman N. Bundesen, president of the health department of the city of Chicago, whose reply follows.]

ANSWER—In 1938 we made a survey of the methods of resuscitation used in Chicago's hospitals. We found that a wide variety of means were employed, including swinging and slapping of the infant, immersion in cold and hot water and the use of various cardiac stimulants, such as epinephrine. At the same time we addressed a letter to leading obstetricians and pediatricians in Chicago asking for their suggestions as to the best methods of resuscitation. The majority of replies were to the effect that the essential things were, first, clearing of the breathing passages using the tracheal catheter when necessary, second keeping the infant warm, third, oxygen, fourth, circulatory stimulants and fifth, the use of the mechanical resuscitator. There seemed to be some general agreement that the use of the Drinker type of resuscitator for infants, particularly the premature infant often resulted in tearing of the air sacs of the lungs. Other positive pressure devices had the same failing. We have had no experience with the more recently developed resuscitators, which furnish both positive and negative pressure but which have automatic controls that shut off the device as soon as the pressure reaches a dangerous point. The obstetricians and pediatricians consulted were in agreement that many of those called on to resuscitate an infant were not familiar with or sufficiently experienced in the use of the tracheal catheter and that training of all those doing obstetrics to employ the catheter properly is a matter of some importance. A study of our records would indicate that possibly many infants do not survive because of faulty methods of resuscitation which are employed, at least these methods contribute to the hazard. In any event there is need for a great deal of further study of this problem.

SYMMETRICAL ENLARGEMENT OF RIGHT ARM

To the Editor—A woman aged 25 has developed a symmetrical enlargement of the right arm during the past year. This arm measures 28 cm at the biceps whereas the left arm measures 21 cm. The tissue is nonedematous and apparently is muscular with visible veins over the anterior biceps near the shoulder. She complains that the right arm tires faster than the left. There is no numbness or tingling of the fingers, the pain sense is normal, the grip is equal in the two hands and all tendon reflexes are increased with no difference in the two arms. Her past history is essentially negative as is her history by systems. The patient is asthenic. The blood pressure is 122 systolic 80 diastolic. The pulse is normal. The abdomen is negative for masses and tenderness. There are no lymph node enlargements. Patellar clonus is present in both legs. An x-ray examination of the chest is apparently normal. This case resembles nothing with which I am familiar. I have considered the possibility of pseudohypertrophic progressive muscular dystrophy but have not heard of its being unilateral. Would you please give an opinion in this case?

V. L. Adams M.D. Myrtle Creek Ore

ANSWER—With the data at hand a definite diagnosis cannot be made. It is unlikely, however, that the condition described is one of pseudohypertrophic progressive muscular dystrophy. The unilateral character, the failure to note dystrophy of the leg muscles and the lack of a familial history are all strong points against this diagnosis.

The history is not clear, moreover, with regard to the extent of the enlargement of the right arm. Measurements are given at the biceps, but it is not clear whether the muscles below the elbow are also involved. With no change in sensation, reflexes or loss of muscular power in the hands, the disease cannot be considered as on a nervous basis with involvement of the peripheral nerves or of the spinal cord. The most likely cause is some obstruction to the vascular or lymph drainage from the arm. This is suggested also by the presence of visible veins over the biceps muscle near the shoulder. The chief cause for such obstruction would be tumor, and the most likely tumor is a sarcoma of the humerus. The same symptoms, however, could be caused by other tumors in and around the shoulder joint or even more centrally placed near the spinal canal. Although the x-ray report of the chest is said to be normal, nothing is mentioned with regard to the roentgenograms of the right shoulder joint or upper arm. These films should be made and possibly a lumbar puncture should be done in order to estimate any blockage in the flow of spinal fluid should the lesion be situated in the spinal canal. If it seems reasonably certain that the muscular tissue is involved, a biopsy of the biceps would be indicated.

PREMENSTRUAL OBSTRUCTION OF NOSTRIL

To the Editor—A white woman aged 42 complains of obstruction of the right nostril accompanied by severe pain in the right nostril radiating to the right side of the forehead. This occurs during the week preceding menstruation and is relieved by menstruation. She also complains of nervousness in the premenstrual week. A good ear nose and throat specialist made an examination roentgenographed her sinuses and told her that she had no sinus trouble or pathologic findings in her nose. Would it be advisable to give roentgen radiation to her ovaries? What other treatment is recommended?

Donald W Todd MD Guthrie Center Iowa

ANSWER—The nasal symptoms may be due to premenstrual edema such as occurs in other parts of the body such as the brain the skin and the intestine where the edema manifests itself as headaches local swellings and abdominal distention respectively. These symptoms subside spontaneously with the onset of menstruation but a simple and inexpensive medication to relieve the symptoms before the menses appear is ammonium chloride. The patient is instructed to take 15 grains (1 Gm) of ammonium chloride (two 7½ grain tablets) after each meal for ten to twelve days preceding the onset of the menstrual flow. During this time she must avoid table salt and all substances and drugs containing sodium such as sodium bicarbonate. If this medication produces relief it should be repeated for a few months in succession. There is no need to castrate this woman for the premenstrual symptoms certainly not until ammonium chloride has been used for a few months (See Greenhill, J P and Freed, S C The Electrolyte Therapy of Premenstrual Distress, THE JOURNAL, Aug 16, 1941, p 504)

GLYCOSURIA AND PROBABLE MILD DIABETES

To the Editor—A physician aged 38 is known to have had a glycosuria for the past fifteen years. The reducing substance in the urine is identified as dextrose by the osazone and fermentation tests. The fasting blood sugar is and always has been within normal limits and the fasting urine is negative for sugar. However following the ingestion of a moderately heavy carbohydrate meal a heavy trace or 1 plus sugar spills over in the urine. Repeated sugar metabolism tests have always shown a normal fasting blood sugar with a return to normal at the expiration of two hours. A glycosuria appears with the elevation of the sugar and sometimes persists and sometimes disappears at the second hour. A dextrose tolerance test performed recently is typical of the tests performed over the past fifteen years and gave the following results: after the ingestion of 150 Gm of dextrose fasting blood 96 mg per hundred cubic centimeters of blood one half hour 167 mg one hour 160 mg two hours 114 mg three hours 71 mg. The urine is reported as fasting negative one half hour trace one hour 3 plus two hours 3 plus three hours negative. Another test following the ingestion of 50 Gm of dextrose followed by the ingestion of a second 50 Gm in one half hour showed fasting blood sugar 97 mg one half hour 205 mg one hour 177 mg with a slight and heavy trace of sugar in the urine at one half and one hour. Is there a discrepancy between these two tests? This man has never developed any other clinical signs or symptoms of diabetes mellitus. He eats normally with no attempt at carbohydrate restriction. He feels perfectly well he leads an active life and his weight has been maintained constantly at 180 pounds (81.6 Kg). Should this be considered as an innocent renal glycosuria or a mild diabetes mellitus? What is the prognosis? Is continued observation of the sugar metabolism indicated? Should this man be physically disqualified from securing a commission in the medical corps reserve?

M D Oregon

ANSWER—The results obtained in the two types of dextrose tolerance tests are roughly comparable in that, although each fails to indicate definitely the presence of diabetes mellitus, in each the values are borderline or suggestive. (It is assumed that the blood sugar values refer to the content of venous blood.) In the first, or standard, type of test the one-half, one and two hour values are just below levels found in mild diabetes mellitus. In the second, or one hour-two dose, test the one hour value of 177 mg is likewise just at the borderline of levels found in diabetes (Matthews M W, Magath, T B, and Berkson, Joseph The One Hour-Two Dose Dextrose Tolerance Test, THE JOURNAL, Oct 21, 1939 p 1531)

The condition is not one of renal glycosuria in the strict sense because sugar does not appear in the urine until the blood sugar has risen to levels approaching the normal (average) renal threshold for sugar.

Any person with glycosuria should be under observation for life and should be warned against the danger of obesity. Under sensible conditions of diet, exercise and general hygiene the prognosis in this case is good provided the physical condition otherwise is sound.

It is recommended that the dextrose tolerance test be repeated using 100 Gm of dextrose by mouth and taking venous blood samples fasting and at one half, one two and three hours. During at least three days prior to the test the patient should eat a diet unrestricted in carbohydrate. At the time of the test the presence of an infection especially with fever or of any nondiabetic condition which might influence the results should be excluded.

Before making a decision as to acceptability for military service the army examiner would probably insist on a test

carried out under standard conditions as outlined. It must be remembered that a person with significant glycosuria, even though not diabetic, may well be rejected because of the nuisance value of such a condition arising from the fact that whenever such a soldier is subjected to physical examination a changing group of army physicians is confronted with the differential diagnosis between harmless glycosuria and diabetes mellitus.

HEMIPLEGIA FOLLOWING INJECTION OF LOCAL ANESTHETIC

To the Editor—A woman aged 45 who had three teeth extracted from the lower left jaw under local infiltration noticed within twenty four hours that the power in her left hand and leg diminished about 50 per cent. She is slightly overweight. The blood pressure is 120 systolic 80 diastolic. The heart lungs and urine are normal. A spinal tap and report on the fluid gave normal results in all findings. Do you think that the procaine hydrochloride could have been injected into a vein which got to the motor centers of the brain? If so how long would it take for the effects to wear off? She is gradually improving and is up and around. Are there any similar cases on record?

M D New York

ANSWER—The character of the solution used and the technique of injection are not mentioned. If an unnecessarily concentrated solution of epinephrine was injected with the local agent, a rise in blood pressure could result. In consequence, the rupture of a small branch of the right middle cerebral artery might account for the weakness. If a severe 'procaine reaction' had occurred, with accompanying disturbance of respiratory or circulatory function, an area in the motor centers on the right side could have suffered sufficient temporary deprivation of oxygen to cause some degeneration of motor cells. Such degeneration might or might not be permanent. 'Fright or fainting' may bring about a similar embarrassment to the blood supply. Unless (1) an extreme rise in blood pressure or (2) a severe respiratory or circulatory crisis occurred during or directly following the injection, the motor disturbance described must be looked on as a coincidence and not related to the injection of a local anesthetic agent.

KIRKLAND'S DISEASE

To the Editor—Recently I had a patient with a clinical picture suggesting the diagnosis of Kirkland's disease (epidemic cervical adenitis). I could get little information about this disease in the usual textbooks of internal medicine. What information I did get I obtained in French's Differential Diagnosis. What is the incubation period of this disease? Have the sulfonamide drugs proved of much value in the treatment? Which one has proved of most value? What type of streptococci is most frequently isolated in throat cultures? I shall appreciate answers to these questions references to the literature and any other pertinent information about this disease.

William M Bush MD New York

ANSWER—No reference to Kirkland's disease, other than the one mentioned, could be found in recent medical literature nor were references found in the systems and textbooks of medicine and of otolaryngology consulted, nor on inquiry did several nationally known internists and otolaryngologists know of such an entity. From the information given in French's Differential Diagnosis the disease appears to be an acute infection of the throat with regional lymphadenitis, to which the person's name who described it has been applied according to an outmoded custom. The statement in the description of the disease implicating streptococci is meaningless, since the kind of streptococci is not specified. Presumably hemolytic streptococci are involved. If so there is no reason to suppose that sulfanilamide or sulfadiazine would not be efficacious in the treatment of this condition.

ALTERNATING CURRENT FOR SHOCK TREATMENT OF PSYCHOSES

To the Editor—In my hospital in the interior of the Belgian Congo I have an 800 watt 32 volt electric plant. Would it be possible and reasonably safe without expensive apparatus to arrange the shock treatment for psychoses in the manner discussed in the Journal of the Missouri Medical Association in the February 1939 issue page 53?

M D Cacao Fla

ANSWER—Alternating current is required for use in connection with electric shock apparatus. Direct current cannot be used. The wattage and voltage of the electric plant described is sufficient for use with any of the commercial electric shock outfits.

RADIUM FOR OFFICE PRACTICE OF OTOLARYNGOLOGY

To the Editor—In Queries and Minor Notes in THE JOURNAL, October 24 page 658 a reply was made to a communication from Dr Charles E Gillespie of Seymour Ind asking where he could obtain radium for office practice of otolaryngology. The reply failed to mention the Canadian Radium & Uranium Corporation 630 Fifth Avenue New York City as another available source of such supply.

INTERDEPENDENCE OF FUNCTION IN ANESTHESIA

WESLEY BOURNE, M.D.
MONTREAL

In words like those of John Dewey, it may be said that functions require the cooperation of organism and environment. Breathing is an affair of the air as truly as of the lungs. The same air that under certain conditions ruffles the pool or wrecks buildings under other conditions purifies the blood and conveys thought. The outcome depends on what air acts on. Function, then, may be regarded as the manner of employing and incorporating the environment. The nature of the surroundings will therefore be bound to have its say. We are subject to ambient influences. Physiologically, it is a fatuity to give precedence to any one vital function or native faculty over another. Each is essential to life. As Edmund Burke has put it, "When we define, we seem in danger of circumscribing nature within the bounds of our own notions, which we often take up by hazard, or embrace on trust, or from out of a limited and partial consideration of the object before us, instead of extending our ideas to take in all that nature comprehends, according to her manner of combining."

And yet it is not altogether inexcusable, teleologically, to give some priority to the functions residing in the blood, which, as Cowdry¹ says, circulates actively as a life-giving, integrating and regulating medium. The regularly circulating blood not only welds the countless numbers of cells into an individual, because it enables all of them to feed at the same table—at the places occupied by their forefathers—and to breathe the same air, but also integrates their activities in many other ways. By providing an efficient medium of intercourse between the cells it has made possible specialization in cellular performances, so that the secretions of the cells of the pituitary for example, passing first into the tissue fluid and seeping through the capillary walls into the blood stream, can influence all the other cells of the body. As cells acquire the ability to do better and better, less and less like individuals in a community, they become dependent more and more on their fellows specialized in other directions. Without the interchanging powers of the blood this dependency on other far distant cells would not be possible.

Thus even to the darksome grove and secret penetralia of the cerebral cortex, where resides the highest of all functions, namely thought, the body fluids are

circulated so that metabolism may take place—even here where are centered those intricate contingencies that knit our lives and those potencies which are coordinated into energy. It is here that in general anesthesia the desired reversible effects take place, so that it would seem, in the language of William James, that the accidental fences which the individual builds are broken and the mind is plunged into the continuum of cosmic consciousness. Although the selective action in general anesthesia is referable to the brain and although there are many theories extant on the mechanism of this action, it is still an open question. Of the whole diadem of hypotheses, that which has to do with the oxidation processes in the brain, the close association between these and cerebral activity, is perhaps the most feasible. Quastel² points out that the gray matter of the brain has a high rate of oxygen consumption and a continuous supply of blood to the brain is essential for the normal functioning of this organ. From six to eight seconds of interruption of cerebral circulation produces loss of consciousness. Herein is a signally definitive instance of interdependence of function: neither the nervous system nor its immediate external environment, the blood stream, could function alone. Without nervous regulation (Cowdry) of muscle the blood would not flow, and without arterial blood the nervous system would soon die. The closest cooperation prevails. The blood stream supplies the cells with the necessities of life, including special stimulating or inhibiting substances contributed by their neighbors, and removes the waste. The nervous system controls the rapid integration of bodily functions by means of nerve impulses. As Gerard³ says, "This universal capacity of protoplasm to hand on excitation is developed into an exquisite talent by the nerve cells. Along their fantastically extended straight processes the nerve impulses, propagated excitation waves, rush to various destinations." Quastel has suggested that an anesthetic is adsorbed from the blood at a specific area or center of the nervous system. Here it hinders the cells of the nervous center from oxidizing pyruvic acid, lactic acid and dextrose. The peculiar effects of anesthetics will depend on the characteristics of adsorption in various parts of the nervous system. It has been shown by Jowett⁴ that a definite inhibition of respiration is produced by anesthetic concentrations sufficient to produce deep narcosis. He states that inhibition of dextrose oxidation may be the cause of anesthesia. Quastel intimates further that anesthetics bring about a local hypoxia in those parts of the nervous system in which they are adsorbed,

despite the presence of oxygen, by virtue of interference with the oxidation of dextrose at a given nervous center. It is not irrelevant to recount the findings of Seller and Mayer,⁵ in effect, respiration is decreased in the cerebral cortex of rats after ether, chloroform and ethyl chloride. These agents do not influence the thalamus or the white matter. Contrarily, evipal soluble decreased respiration of white matter and thalamus but did not affect that of the cerebral cortex.

This may be illustrated the influence of anesthetics on function in the central nervous system when these are in solution in the blood. But the functions of the circulating blood may themselves be disturbed in anesthesia. A striking example is seen in high spinal anesthesia when breathing is depressed, when the heart is slowed when the blood pressure falls and when there is blood dilution, in other words, when the circulation becomes sluggish and the oxygen-carrying power of the blood is reduced. Then, in the light of interdependence of function, the central nervous system will be robbed in part of its most important substrate, dextrose, and, as well, be deprived of its proper supply of oxygen, both so vitally important for purposes of internal respiration. The brain demands at least a minimum concentration of dextrose and a constant supply of oxygen.

With regard to external respiration, Gesell⁶ draws attention to the fact that rapid adjustments in the exchange of carbon dioxide for oxygen depend on pulmonary ventilation and the circulation of the blood. These two systems function in harmony under similar influences at and from the respiratory and the circulatory centers and their outlying chemoceptors. By themselves, the chemical mechanisms, central and peripheral, are capable of acting efficiently. Complementary control obtains through the physical forces of stretchings of the carotid sinus, the aortic arch and the proprioceptive endings in the lungs. Whether caused by hypoxia or hypercapnia, hyperpnea signifies impaired oxidation or increased H ion concentration, or both, at the chemosensitive structures. There is evidently a very finely adjusted interaction. However, the part played by reflex factors in influencing pulmonary ventilation has been demonstrated by Harrison⁷ on anesthetized animals in which hyperpnea occurred when a limb was moved passively, even though the blood was intercepted and the leg was connected with the body only by the sciatic nerve. When the sciatic nerve was cut, movements of the leg no longer affected breathing even though vascular communications were reestablished. How pervadingly interwoven and abundant is function between the nervous system the circulation and respiration. To consider any one without the others is to be blind and halting.

On account of the regard that anesthetists have always had for the functions of the liver and the kidney, something may be said of their interpenetration. The superfluity of structure in these organs, the reserve of power they possess and the integration of their activities through the blood stream, through nerve influences and hormone essences, are so bewildering and so extensive that I can do no more at this time than to exemplify a little. Despite disparate structure, functions are correlated in action whether they are acquired with seem-

ingly reasoned purpose or are innate, spontaneous and altogether inconscient. Recently Van Slyke⁸ has followed some of the paths in the body that are taken by amino acids after digestion and absorption in the alimentary tract. Among other things, he says that "one could watch the work of the liver in taking up the amino acids and destroying them, turning their nitrogenous parts into urea for excretion by the kidneys. Unreasonable and wasteful though it seems, a large part of the amino acids absorbed from the intestine appears to be captured and destroyed by the liver and never to have a chance to reach and nourish the other tissues." It is interesting parenthetically to posit beside this statement one by Carlson⁹ "The normal kidneys are very effective regulators of the composition of the internal environment, the blood, but fail to eliminate excess thyroxin, excess parathyroid hormone, excess pituitary growth hormone, and also excess insulin. Is this a failure in evolution? Or are we just on the way?" According to Van Slyke, it would appear that every protein molecule in the living body is itself alive in the sense that it is continually changing and renewing its structure through the continual replacement of amino acids. The detoxifying effects of the amino acids have been known for some time and we are now all familiar with Quick's¹⁰ hippuric acid test for liver function. Incidentally, it is not inappropriate to say that anesthetists ought to know the liver function tests so clearly set forth by Mateer and his associates.¹¹ It may be worth while pointing out that the liver transforms amino acids into dextrose,¹² that this organ stores protein against the occasion of starvation or hemorrhage,¹³ that the Russian chemists Braunstein and Kritzman,¹⁴ have shown that the amino acids can be constructed from ammonia and keto acids, that, by transmethylation from methionine, the essentials choline and creatine are made in the body,¹⁵ that the sulfur-containing amino acids cystine and methionine protect the liver from intoxication by chloroform,¹⁶ that when the reserve tissue proteins are depleted by fasting and the plasma proteins are depleted by bleeding¹⁷ the proteins can be rapidly restored in tissues and plasma by intravenous amino acid administration, which might be suitable at times when feeding by mouth is impossible or inadvisable, and that, by condensation, by oxidation-reduction reactions and in more profound ways,⁸ the amino acids "can serve as source material for certain vitamins, hormones and other compounds with physiological function still to be identified."

Furthermore, I know of no better instance of effort toward interdependence of function than that which occurs in the kidneys of anesthesia when phosphoric acid leaves the muscles, travels through the blood and sojourns in the liver until such time as kidney function is reestablished, during recovery, when it is partly redistributed and partly excreted¹⁸

With all these interdependent chemiophysiological links before one and other unimaginable superabundant and minute adaptations of functioned tissue, correlated delicately in a raveled web there comes to the non-Philistine mind a consideration of the disturbances which may occur on account of anesthesia, particularly now in circumstances of war, when there are so many shocked patients whose conditions demand immediate surgical intervention and in whom that Gordian knot of the physician in wartime, the vicious circle of shock, has all too often to be dealt with. It becomes a matter of particular importance, therefore, continually to bear in mind what is known of the conduct of shock and what is known of the effects of the drugs used in anesthesia. To illustrate let me draw attention to some of the actions of ether: how it causes a sharp reduction in the volume of the blood and a relatively large increase in the interstitial fluid,¹⁹ how it causes the blood solids to increase by 2 to 3.5 per cent of the total weight of the blood while the individual tends to become poikilothermic,²⁰ how it produces an immediate depression of function in the liver²¹ and kidney,²² and how it invariably precipitates a true acidosis.²³ Surely these are enough to suggest that ether ought not to be given to a patient in shock during which fluid is leaking into the tissue spaces to such an extent that blood volume may be so dangerously lowered as to deprive the blood vessels of sufficient fluid for circulation. The administration of ether will undoubtedly increase the breakdown in the interdependence of function seen in shock.

With regard to hypoxia the respiratory depressant action of many anesthetics is thought to be, at least in part, due to a reduction in sensitivity of the respiratory center. It is not unlikely that when in shock the respiratory center is already suffering from anoxia and any one of many narcotic drugs may lead to its earlier failure. Substances which reduce the effective ventilation may harm the shocked patient, since the reduction in ventilation of itself will tend to increase the existing tissue hypoxia from which the whole organism is being affected. It is clearly undesirable to allow further disturbance of the metabolism from an increase in oxygen want, when the individual may have already passed the nadir of depression.

While this is not a discourse on shock, it is not altogether inapposite to say that the "local" and "block" forms of regional anesthesia seem to be especially suitable for cases of shock and that, no matter what the method of anesthesia, one is well advised regularly and actively to give oxygen throughout the administration.

One might go on interminably, even to that interdependence of function seen in the dead parts of our beings, such as the body fluids, including the great fluid fractions of lymph and blood, which like the wood walls and tubes of the higher plants are highly serviceable to the organism.

Finally, for all interpenetration of function, some simile may be seen in the words of George Santayana. Mind owes its origin, growth, and development to matter, but the strange child repays his parent a hundredfold with the riches he pours in her lap. Nature gives birth to consciousness; consciousness gives value to nature."

32 Holton Avenue Westmount

ABSTRACT OF DISCUSSION

DR RALPH M. WATERS, Madison, Wis. I gather that what Dr. Bourne has been saying is that the effects of administration of an anesthetic agent cannot be tabulated as simple stimulation of one function and depression of another but that, in addition, there is likely to be a secondary effect on a second function caused by the stimulation or depression of the first and not necessarily caused directly by the anesthetic drug. As a common example if the agent per se causes a depression of respiratory exchange there will result a depletion of the oxygen content of the blood. This hypoxia in turn will put an extra strain on the heart in an attempt to bring about an increase in cardiac output. If the heart is lacking in adequate reserve strength circulatory failure may follow. The unhappy result in such a case would not be a direct effect of the anesthetic agent per se but rather it would furnish evidence of the reciprocal relationship and interdependence of the two functions of respiration and circulation. Dr. Bourne has called to our attention many such relationships and he has by no means exhausted the instances of interdependence. There is scarcely a single function of the body that, when modified by anesthesia, fails in its modified condition to have an effect on other physiologic mechanisms. To simplify the teaching of the pharmacologic effects of anesthetic drugs, I have been guilty—along with others—of trying to make a table listing the agents and, in columns following them, the various organs or functions of the body. Under each organ or function was placed the characteristic effect of each drug. The result was anything but fortunate. To correlate the contents of the table with observations made during the administration of an anesthetic was often difficult or impossible. We must continue to observe and record, watch closely what we see of functional change during anesthesia, write down our impressions at the time, familiarize ourselves with the evidence from the laboratories as it appears in the literature and hope that, by keeping everlastingly alert, we may improve our understanding of functional disturbances caused by anesthetic drugs directly, and of the secondary changes in other functions resulting from the interrelationships which Dr. Bourne has indicated.

DR RALPH M. TOVELL, Hartford, Conn. It is with profit that we have listened to Dr. Bourne's presentation of the circuitous and interwoven relationships of human physiologic functions. The need for further research to unravel the interrelationships of function has been amply demonstrated. He has succeeded admirably in showing that an anesthetist's thought patterns during administration of an anesthetic should not be limited to either respiratory function or circulatory function but should encompass the body as a single working unit. He stated the crux of the problem when he said "How pervasively interwoven and abundant is function between the nervous system, the circulation and respiration. To consider any one without the others is to be blind and halting." We as clinicians can second Dr. Bourne's implied appeal for continuance of unrelenting effort in research. Those of us without laboratory facilities are duty bound to have within our ken the information that has already been proved to be factual.

POSTDIPHTHERITIC LARYNGEAL
STENOSISSIMON JESBERG, M.D.
LOS ANGELES

Obstructions of the larynx herein considered are those which are brought about by changes in the intralaryngeal tissue or the supporting framework. These are essentially chronic and are the sequelae or end results of some acute inflammation or injury.

While the term laryngeal stenosis is used, actually the site of obstruction is most often subglottic and frequently extends for a variable distance into the upper part of the trachea. Stenoses of this type are almost invariably in the region of the conus elasticus, which has for its upper limit the vocal cords and extends down through the subglottic region to become blended with the lining of the upper part of the trachea. In this region there is areolar tissue surrounding the conus elasticus, which is more abundant in young children than in older persons. Swelling of this tissue is easily provoked by inflammation and trauma, thereby causing acute obstruction of the airway. This occurs in inverse

ratio to the age of the patient. When this area is involved in inflammatory reaction, regardless of the cause, it is particularly intolerant of instrumentation. Thus violent reactions occur which are out of all proportion to the apparently trivial trauma following the passage of bronchoscopic tubes in young children with preexisting laryngitis. Reactions such as these are seen particularly in children under 2 years of age, and tracheotomy is often necessary to prevent suffocation. If intubation is preformed a reaction such as is encountered in bronchoscopy will occur, but as long as the tube remains in situ it will forcibly maintain open passage. However, if for any reason the tube is taken out or is extruded before the reaction subsides, there will be a tendency for the lumen of the larynx rapidly to become obstructed.

Obstructions due to acute laryngeal inflammation may disappear spontaneously, or there may be subsequent tissue changes that will ultimately lead to chronic stenosis. These tissue changes are persistent swelling and hypertrophy of the subglottic tissue, necrosis and granulation tissue proliferation and the production of cicatricial tissue. These three processes may be present singly or in varying combinations. The laryngeal framework may also be involved, which adds to the gravity of the situation.

CAUSE

By far the most common cause of laryngeal stenosis is diphtheria.

This report is concerned mainly with the group of patients with laryngeal stenosis in the contagious service of the Los Angeles General Hospital during the last twenty-two years, a group which was under my supervision during this time (1920-1942).

According to the records of the Los Angeles County Board of Health, there were 40,107 cases of diphtheria diagnosed during the period from 1920-1942, 10,402 of these were treated in the general hospital, 1,744 of which were cases of laryngeal diphtheria. In this group there were 448 deaths, 1,296 patients survived and were discharged from the contagious ward. Of the survivors, 108 were referred to the laryngologic department for treatment of laryngeal obstruction. The patients of this group ranged in age from 13 months to 3½ years, the average age being under 2 years. The obstruction in all these cases was mainly below the true cords, that is, in the subglottic area involving the region of the conus elasticus. Ninety of this group of 108 patients were wearing tracheotomy tubes and the remaining 18 were breathing through the larynx with varying degrees of difficulty. Eleven patients with tracheotomy tubes also had minor degrees of obstruction. In the 2 latter groups of 29 patients persistent subglottic swelling was treated by galvanocautery puncture. All these patients recovered in a few weeks or months. The remaining 79 patients, all wearing tracheotomy tubes, had varying degrees of severe laryngeal obstruction. In these patients the lumen was obstructed by granulations and there was necrosis of the soft tissue. As healing progressed the tendency to scar tissue formation became increasingly more evident.

At weekly intervals the lumen was tested by closing the tracheotomy tube with a finger. Instrumentation was limited to direct laryngeal examination and the passing of a laryngeal sound to test the size of the lumen. The retrograde sounds of Lynah were found particularly useful. Exuberant granulations were partially removed. If the tonsils and adenoids were infected, their removal was advised. Dilating rubber sections were not inserted until the healing process was fairly well advanced.

It is during the healing stage of such cases that utmost judgment in treatment must be exercised. In this phase there is an optimum amount of treatment that should be effected in order to produce satisfactory results. If this optimum is exceeded by over strenuous dilation or excessive traumatization to the already inflamed structures, one runs the risk of augmenting the condition. On the other hand, if dilation therapy is not started at this stage or soon after the patient is almost certain to end up with a grossly stenosed or obstructed larynx. Obviously, therefore, the technic in successfully handling these cases centers around an accurate estimation of the condition of the larynx and its toleration to subsequent treatment. In any case which does not fit into a treatment category it is probably best to proceed very cautiously with minimal dilation at first in order to remain under the threshold of the secondary reaction due to overintensive therapy.

Notwithstanding our best efforts, 28 of this group ultimately had complete stenosis and required a tracheo-

laryngostomy operation. Four of the 108 patients died during the course of active treatment: 1 with intercurrent disease, 1 from suffocation when his tracheotomy tube came out at home, 1 from lung and brain abscess and 1 with pneumonia.

Treatment of laryngeal stenosis has for its objective the establishment of a permanent and adequate airway.

Fig 1—Rubber section ready to be drawn into the larynx.

through the larynx. This is accomplished by protracted treatment with some dilating device which is introduced into the larynx.

Of all the various dilating devices thus used, soft rubber in the form of tubing or coremolds has been found most satisfactory. Soft rubber is well tolerated by the laryngeal tissue and also has the property of increasing slightly in size while in the larynx, thus exerting continuous gentle but firm pressure.

In order to be satisfactory, treatment must be accomplished with a minimum of injury. Since patients in this category are small children, especial care must be exercised to prevent psychic trauma. This calls for some method whereby these treatments can be carried out with a minimum of pain and discomfort.

The method here described was devised for the introduction of rubber sections into the larynx through a small tracheal stoma or through a tracheotomy wound.

Rubber sections are made from urethral catheters size 20 to 30 French. They are cut about $2\frac{1}{2}$ inches long, are beveled at both ends on an emery wheel and are marked with their size with silver nitrate.

The introducer is made from a rubber urethral catheter. The dilated end with about 8 inches of the catheter is used. A metal stylet is inserted into the lumen filling all but 2 inches of the flared end. To the cut end of the tube is fastened a metal cap or ferrule that has a smooth conical end. The stylet is bent so that the curve of the catheter describes an arc of a 6 inch radius. It is an easy matter to introduce this device through the tracheotomy wound, as it appears in the mouth it is grasped, and the section which has previously been placed in the flared end is drawn into the larynx. Holding the section in situ with a forcep through the tracheotomy wound, the introducer is completely withdrawn from the mouth, leaving the laryngeal section in the larynx.

PRELIMINARY PREPARATION OF THE SECTION

The length of the section is determined by calculating the distance from the upper part of the cricoid to the upper margin of the tracheotomy wound. After a proper length has once been found it is used as a guide in preparing future sections. The lower end of the section is cut on a slant with scissors so as to fit the curve of the tracheotomy tube. A silkworm gut suture on a needle is passed through the anterior wall of the section and tied, the ends being left free to be attached to the tracheotomy tube. After the section has been placed in the larynx the sutures emerge from the tracheotomy wound. These are threaded onto the tracheotomy tube before it is inserted. The tracheotomy tube is a standard one which has been modified by having a breathing opening placed in the greater curvature, just anterior to this opening is a small metal loop. The free suture ends having been passed through this loop one from each side, are tightened as the tracheotomy tube slips into place, thus anchoring the section and tube into one unit. The sutures are finally brought through small holes in the guard where they are tied.

The period of time these rubber sections are left in place is important. If they are changed too frequently there is added trauma to the tissues and epithelization of the passage is retarded. If left too long, they become foul and contribute to the inflammation. Calcareous salts become encrusted on the tube in six weeks. The best results were found by changing the section every three weeks.

Most of the patients with incomplete stenosis were able to dispense with treatment at the end of twelve months. Several were cured in a much shorter period, the shortest time being three months. Four patients are still under treatment after five years. In cases of cicatricial stenosis, the period of active treatment exceeded eighteen months. After this the patients were kept under continued observation. Recurring stenosis was treated by a short period of dilation with rubber

Fig 2—Rubber section in place, note compression of the anterior wall of the section by constricting scar tissue.

sections. These children have developed quite normally. The tracheal opening was covered with a patch of adhesive and permanent closure was deferred until further growth of the larynx, which in more than half of the severe cases was not until the age of puberty. An increase in the size of the larynx by growth of the supporting framework is an important factor for a

POSTDIPHTHERITIC LARYNGEAL
STENOSISSIMON JESBERG, M D
LOS ANGELES

Obstructions of the larynx herein considered are those which are brought about by changes in the intralaryngeal tissue or the supporting framework. These are essentially chronic and are the sequelae or end results of some acute inflammation or injury.

While the term laryngeal stenosis is used, actually the site of obstruction is most often subglottic and frequently extends for a variable distance into the upper part of the trachea. Stenoses of this type are almost invariably in the region of the conus elasticus, which has for its upper limit the vocal cords and extends down through the subglottic region to become blended with the lining of the upper part of the trachea. In this region there is areolar tissue surrounding the conus elasticus, which is more abundant in young children than in older persons. Swelling of this tissue is easily provoked by inflammation and trauma, thereby causing acute obstruction of the airway. This occurs in inverse

ratio to the age of the patient. When this area is involved in inflammatory reaction, regardless of the cause, it is particularly intolerant of instrumentation. Thus violent reactions occur which are out of all proportion to the apparently trivial trauma following the passage of bronchoscopic tubes in young children with preexisting laryngitis. Reactions such as these are seen particularly in children under 2 years of age, and tracheotomy is often necessary to prevent suffocation. If intubation is preformed a reaction such as is encountered in bronchoscopy will occur, but as long as the tube remains in situ it will forcibly maintain open passage. However, if for any reason the tube is taken out or is extruded before the reaction subsides, there will be a tendency for the lumen of the larynx rapidly to become obstructed.

Obstructions due to acute laryngeal inflammation may disappear spontaneously, or there may be subsequent tissue changes that will ultimately lead to chronic stenosis. These tissue changes are persistent swelling and hypertrophy of the subglottic tissue, necrosis and granulation tissue proliferation and the production of cicatricial tissue. These three processes may be present singly or in varying combinations. The laryngeal framework may also be involved, which adds to the gravity of the situation.

CAUSE

By far the most common cause of laryngeal stenosis is diphtheria.

This report is concerned mainly with the group of patients with laryngeal stenosis in the contagious service of the Los Angeles General Hospital during the last twenty-two years, a group which was under my supervision during this time (1920-1942).

According to the records of the Los Angeles County Board of Health, there were 40,107 cases of diphtheria diagnosed during the period from 1920-1942, 10,402 of these were treated in the general hospital, 1,744 of which were cases of laryngeal diphtheria. In this group there were 448 deaths, 1,296 patients survived and were discharged from the contagious ward. Of the survivors, 108 were referred to the laryngologic department for treatment of laryngeal obstruction. The patients of this group ranged in age from 13 months to 3½ years, the average age being under 2 years. The obstruction in all these cases was mainly below the true cords, that is, in the subglottic area involving the region of the conus elasticus. Ninety of this group of 108 patients were wearing tracheotomy tubes and the remaining 18 were breathing through the larynx with varying degrees of difficulty. Eleven patients with tracheotomy tubes also had minor degrees of obstruction. In the 2 latter groups of 29 patients persistent subglottic swelling was treated by galvanocautery puncture. All these patients recovered in a few weeks or months. The remaining 79 patients, all wearing tracheotomy tubes, had varying degrees of severe laryngeal obstruction. In these patients the lumen was obstructed by granulations and there was necrosis of the soft tissue. As healing progressed the tendency to scar tissue formation became increasingly more evident.

At weekly intervals the lumen was tested by closing the tracheotomy tube with a finger. Instrumentation was limited to direct laryngeal examination and the passing of a laryngeal sound to test the size of the lumen. The retrograde sounds of Lynah were found particularly useful. Exuberant granulations were partially removed. If the tonsils and adenoids were infected, their removal was advised. Dilating rubber sections were not inserted until the healing process was fairly well advanced.

It is during the healing stage of such cases that utmost judgment in treatment must be exercised. In this phase there is an optimum amount of treatment that should be effected in order to produce satisfactory results. If this optimum is exceeded by over strenuous dilation or excessive traumatization to the already inflamed structures, one runs the risk of augmenting the condition. On the other hand, if dilation therapy is not started at this stage or soon after the patient is almost certain to end up with a grossly stenosed or obstructed larynx. Obviously, therefore, the technic in successfully handling these cases centers around an accurate estimation of the condition of the larynx and its toleration to subsequent treatment. In any case which does not fit into a treatment category it is probably best to proceed very cautiously with minimal dilation at first in order to remain under the threshold of the secondary reaction due to overintensive therapy.

Notwithstanding our best efforts, 28 of this group ultimately had complete stenosis and required a tracheo-

laryngostomy operation. Four of the 108 patients died during the course of active treatment: 1 with intercurrent disease, 1 from suffocation when his tracheotomy tube came out at home, 1 from lung and brain abscess and 1 with pneumonia.

Treatment of laryngeal stenosis has for its objective the establishment of a permanent and adequate airway.

Fig 1—Rubber section ready to be drawn into the larynx

through the larynx. This is accomplished by protracted treatment with some dilating device which is introduced into the larynx.

Of all the various dilating devices thus used, soft rubber in the form of tubing or corin molds has been found most satisfactory. Soft rubber is well tolerated by the laryngeal tissue and also has the property of increasing slightly in size while in the larynx, thus exerting continuous gentle but firm pressure.

In order to be satisfactory, treatment must be accomplished with a minimum of injury. Since patients in this category are small children, especial care must be exercised to prevent psychic trauma. This calls for some method whereby these treatments can be carried out with a minimum of pain and discomfort.

The method here described was devised for the introduction of rubber sections into the larynx through a small tracheal stoma or through a tracheotomy wound.

Rubber sections are made from urethral catheters size 20 to 30 French. They are cut about $2\frac{1}{2}$ inches long, are beveled at both ends on an emery wheel and are marked with their size with silver nitrate.

The introducer is made from a rubber urethral catheter. The dilated end with about 8 inches of the catheter is used. A metal stylet is inserted into the lumen filling all but 2 inches of the flared end. To the cut end of the tube is fastened a metal cap or ferrule that has a smooth conical end. The stylet is bent so that the curve of the catheter describes an arc of a 6 inch radius. It is an easy matter to introduce this device through the tracheotomy wound, as it appears in the mouth it is grasped, and the section which has previously been placed in the flared end is drawn into the larynx. Holding the section in situ with a forcep through the tracheotomy wound, the introducer is completely withdrawn from the mouth, leaving the laryngeal section in the larynx.

PRELIMINARY PREPARATION OF THE SECTION

The length of the section is determined by calculating the distance from the upper part of the cricoid to the upper margin of the tracheotomy wound. After a proper length has once been found it is used as a guide in preparing future sections. The lower end of the section is cut on a slant with scissors so as to fit the curve of the tracheotomy tube. A silkworm gut suture on a needle is passed through the anterior wall of the section and tied, the ends being left free to be attached to the tracheotomy tube. After the section has been placed in the larynx the sutures emerge from the tracheotomy wound. These are threaded onto the tracheotomy tube before it is inserted. The tracheotomy tube is a standard one which has been modified by having a breathing opening placed in the greater curvature, just anterior to this opening is a small metal loop. The free suture ends, having been passed through this loop one from each side, are tightened as the tracheotomy tube slips into place, thus anchoring the section and tube into one unit. The sutures are finally brought through small holes in the guard where they are tied.

The period of time these rubber sections are left in place is important. If they are changed too frequently there is added trauma to the tissues and epithelization of the passage is retarded. If left too long, they become foul and contribute to the inflammation. Calcareous salts become encrusted on the tube in six weeks. The best results were found by changing the section every three weeks.

Most of the patients with incomplete stenosis were able to dispense with treatment at the end of twelve months. Several were cured in a much shorter period, the shortest time being three months. Four patients are still under treatment after five years. In cases of cicatricial stenosis, the period of active treatment exceeded eighteen months. After this the patients were kept under continued observation. Recurring stenosis was treated by a short period of dilation with rubber

Fig 2—Rubber section in place note compression of the anterior wall of the section by constricting scar tissue

sections. These children have developed quite normally. The tracheal opening was covered with a patch of adhesive and permanent closure was deferred until further growth of the larynx, which in more than half of the severe cases was not until the age of puberty. An increase in the size of the larynx by growth of the supporting framework is an important factor for a

good ultimate result. All these children have audible voices, although rather rough and low pitched. Those in this group who continued with minor degrees of laryngeal obstruction had adequate airways after the age of puberty. Only 1 patient of this group is still wearing a tracheotomy tube after puberty.

There is a decided decrease in the incidence of diphtheria in Los Angeles County, as shown in table 2 compiled from the records of the board of health and the general hospital.

Virulence of diphtheria infections has also shown a decided decrease. The percentage of laryngeal involvement has decreased two thirds.

In the five year period 1922-1927, of all diphtheria patients in the contagious pavilion 152 per cent had laryngeal infection. In the period 1937-1942 this had

decreased to 54 per cent. The last cicatricial stenosis in this service occurred in 1936, and since that date there have been referred only 5 other cases, all presenting minor degrees of laryngeal obstruction.

Postdiphtheritic stenosis is rarely seen in private practice. During this time I saw only 3 such cases which were treated outside of the hospital. The diphtheria staff of the Los Angeles County Board of Health feels that most severe laryngeal diphtheritic infections in young children cause death unless the children are given institutional treatment.

The Los Angeles General Hospital is the only institution in the county that treats contagious diseases. The 10,402 diphtheria patients treated in this hospital during the period 1920-1942 constituted about one fourth of all cases of diphtheria occurring in the entire county. All patients with resultant laryngeal stenosis from this group were referred to the eye and ear hospital for treatment, which was carried out under my supervision.

500 South Lucas Avenue

ABSTRACT OF DISCUSSION

DR FLETCHER D. WOODWARD, Charlottesville, Va. Los Angeles County is to be congratulated on a very active campaign of immunization, since these cases have dropped from a maximum of 4,000 a year to a maximum of around 180 to 200 in the past few years. In my experience I have felt that the use of the intubation tube has played some role in the creation of stenosis. I still advocate intubation, and I believe that it is the method of choice in the treatment of laryngeal diphtheria. I have made it a rule that, if there is any difficulty as a result of using the intubation tube, tracheotomy should be done. I think that this procedure will reduce the incidence of stenosis. As to treatment, Dr. Jesberg had an ingenious method and a successful method, as his statistics will prove. I have not used this method, but I expect to employ it in 2 or 3 cases which I have under my care at this time. I have been using the dilators of Jackson, and I have recently used the dilators of Dr. Broyles but these only dilate at the time one is using them, and one does not get the effect of the continuous pressure of rubber in this area. I have used the rubber tube for other types of stenosis after the method of Schmieglow, and I believe that rubber is the answer to many of these problems.

DR M. F. ARBUCKLE, St. Louis. Most of us do not have an opportunity to see as much material as the author has had. There are two or three points that I should like to call attention to, with regard to etiology. He mentioned the virility of the organism and intubation. Ill fitting intubation tubes of course, traumatize the larynx, which is already infected. When one uses an ill fitting intubation tube one is certain to have a tracheotomy, and it is usually a hurry-up one. Nobody can do one in a hurry as well as one can do it when one has time to set it up. I was astonished when I read Schmieglow's Semon lecture on cicatricial stenosis. I was astonished with the ease of mind, apparently, with which he opened and reopened the larynx, when he wanted to work in it, without apparent injury or arrested development. It is true that the lumen of the larynx grows as the child develops. In these cases in which the lumen is closed, it is, of course, not possible to pull up a prosthesis from below or to put it down from above. In those I like to open the larynx and implant the rubber prosthesis and sew the larynx together practically over it. That is where judgment is required not to get pressure too great or too little. I have not seen any of these cases since I entered military service but I heard of one man in whose neck I implanted a rather large rubber tube six months or a year before I left home for an almost complete stenosis due to a razor cut. He had finally reached the point that, by wearing the rubber tube he had a lumen wide enough so that he could get along without the tube. I am sure absorption takes place from the constant pressure. I would be interested to know, at some other time the results any of you have had, if you would communicate with me personally with the use of skin grafts intratracheally, in the effort to prevent adhesions and deformity.

DR SYMON JESBERG, Los Angeles. When I started this paper I had in mind cicatricial stenosis from all causes, but as I progressed I saw that that would be much too voluminous a paper to present in such a meeting so I stuck to the diphtheritic but this same method of introducing the rubber sections is very useful in cases of fractures of the larynx after reduction in which one wishes to hold the larynx in place, or, in a cut throat with cut trachea, they can be introduced through a low tracheotomy wound, holding the trachea in proper alignment until healing takes place. The matter of dilating the larynx of young children is a simple thing, and one can get a lumen large enough in a short time, but it will not remain patent. One must wait until the laryngeal framework supports that lumen, so there is a period in children extending sometimes over many years until that growth occurs. The high tracheotomy is included in the paper as one of the common causes. Another cause that I am running across occasionally is chondritis and collapse of the larynx following laryngeal fissure operation in which this same method is used after complete healing has occurred.

THE EXCRETION OF NICOTINE IN
BREAST MILK AND URINE FROM
CIGARET SMOKING

ITS EFFECT ON LACTATION AND THE NURSING

H HARRIS PERLMAN, MD

AND

ARTHUR M DANNENBERG, MD

WITH THE TECHNICAL ASSISTANCE OF

NATHAN SOKOLOFF, BA

PHD WILLIAM

The rapid and somewhat startling increase in the consumption of cigars in the United States by both males and females during the past decade (1931 113,500,000 000, 1941, 189,769,000,000) has caused many investigations to determine whether cigaret smoking is harmful. Reports of these investigations are, for the most part, conflicting, making it extremely difficult for physicians to evaluate properly the evidence and to advise their patients on the use of cigars in disease and in other conditions. Particularly is this true with regard to cigaret smoking by pregnant and parturient women, for the effects of nicotine on the fetus and the newborn infant must be seriously considered. No definite scientific evidence of the effect of cigaret smoking on the human fetus is available. Recently, however, Schoenbeck¹ in an interesting experiment with rabbits showed that exposing pregnant rabbits to the smoke of 1 cigaret a day resulted in litters that had a birth weight approximately 17 per cent less than those of the control litters. The stillbirth rate was ten times as great and the mortality rate was definitely increased, since only one third as many offspring of mothers exposed to smoke were alive at maturity.

A study of the effect of cigaret smoking by parturient women on lactation and on the nursing has been made by many—again with conflicting results. Thompson,² from a review of the literature and from personal observation, believes that smoking in moderation probably is a minor factor in influencing lactation. He has not observed, however, a patient averaging 8 or more cigars daily whose lactation was adequate at three months after delivery.

Hatcher and Crosby³ noted in a primipara aged 25 who smoked 20 to 25 cigars daily that the secretion of milk, while abundant at first, rapidly decreased, so that a sample of milk was collected with difficulty after 7 cigars had been smoked within two hours. They found experimentally that large doses of nicotine suppress the secretion of milk in the cat and cow for longer periods than the time required for the elimination of the greater part of the poison from the body.

Mgalobeli⁴ noted that in women employed in tobacco factories there occurred a decided decrease in the

number of pregnancies and an increase in the frequency of miscarriages and infant deaths, all of which he attributed to the direct and indirect effects of nicotine on the sex organs. On the other hand, Chiasson⁵ found exceptional fertility and lactation in a group of French families the women of which were habitual and constant pipe smokers. H C Williamson, H S McCandlish, and Ogden Conkey, all of the department of obstetrics of Cornell University Medical College, informed Hatcher and Crosby that they never observed any diminution in the secretion of milk or any effects on a child which could be attributed to the smoking of cigars by the mother.

Perhaps one of the best investigations on this subject was made by Emanuel⁶ in a study of nicotine in the milk of 10 women following the smoking of tobacco. He found that after smoking cigars nicotine passes in slight amounts into the milk and in much larger amounts into the urine. The nicotine could, at times, be demonstrated one to two hours after smoking, but the main excretion appeared four to five hours after smoking, and in some cases it was still demonstrable seven to eight hours after smoking. The largest amounts of nicotine appeared in the milk when the tobacco smoke was inhaled. A study of the infants when they were fed this nicotine-containing milk revealed that the feces remained unchanged. In 1 child, however, the consistency of the feces changed somewhat, but no general effect occurred. The feces of another child, whose mother was made to smoke 20 cigars within four hours, became abnormal following the ingestion of the nicotine-containing milk. Smoking cigars did not influence the quantity of milk produced. This was in disagreement with Sokolov, who found that lactation was inhibited by nicotine. It seemed to Emanuel rather striking that, with the exception of a questionable effect on the intestine, observed in 2 cases, no changes were observed in the infants following the ingestion of nicotine-containing milk. It was questionable whether the amounts of nicotine contained in the milk could be considered toxic doses. He stated that, according to Erben, the lethal dose of nicotine for an adult is 50 mg and that Schroff demonstrated on himself that the first toxic symptoms appear after the intake of 1 to 4 mg of nicotine. Since these studies had shown that a maximum of 0.03 mg of nicotine per liter of woman's milk was found after the smoking of 7 to 15 cigars, the infant would have to ingest an entire liter of this milk to take up but 0.03 mg of nicotine, which is an amount below the toxic threshold. The practical conclusion drawn by Emanuel from these observations was that the physician might permit a lactating mother to smoke 5 to 6 cigars a day, since this amount could not produce any injurious effect on the infant. Any excessive smoking must be prohibited, since following the smoking of more than the 15 cigars the amount of nicotine passing into the milk may have an injurious effect on the child.

Since the average nicotine content of the American blend type of cigaret is 2.5 per cent,⁷ the difficulties of detecting and accurately estimating the minute quantities of nicotine secreted in the breast milk and urine after a variable number of cigars have been smoked become

apparent. For the standard colorimetric and chemical tests, large quantities of milk and urine are required, and if the amounts of nicotine are very small they may escape detection. Hatcher and Crosby³ used the frog for a bio-assay of nicotine in their investigations. This method, somewhat modified, was also used by Thompson in his analysis of milk for nicotine. The frog method for nicotine estimation is a very delicate, qualitative test but gives only a rough quantitative estimate. In Emanuel's study leech segments were used to demonstrate the presence of nicotine in milk and urine by means of Fuhner's method.

In our study, small, transparent, fresh water crustaceans, *Daphnia magna*, belonging to the Cladocera, were used. Their well developed muscular, nervous and internal organ systems make direct observation of them under normal conditions and under the influence of various drugs extremely easy. Hence they are ideal for the bioassay of various substances. They have already been used to assay strychnine,⁸ aphrodisiacs,⁹ vitamin E,¹⁰ digitalis¹¹ and many other drugs.¹²

The propagation of *Daphnia* has been reported by Viehoever¹³ and the methods of standardization have been given by Viehoever and Cohen.⁸ Cultured under uniform conditions, *Daphnia magna* exhibits a definite rhythm and periodicity of growth. In the series of experiments to be described, *Daphnia* was grown in 0.75 per cent to 0.1 per cent infusion of cow manure (bovung). This method of culture was chosen in preference to other methods because it yielded animals with greater amounts of pigmentation, which facilitated their observation in milk. Reproduction is chiefly through diploid parthenogenesis, hence numerous offspring of genetic uniformity are thus assured.

It was found that *Daphnia* is extremely sensitive to minute amounts of nicotine, although its effects vary with the age and sex of the animal. In low concentrations younger animals are more sensitive than the older ones. The males are more sensitive than the females. An increase in temperature from 15.5 C to 32.2 C also increases the sensitivity. Below 15.5 C these crustaceans are sluggish; above 32.2 C they become debilitated. It is therefore important to perform experiments at an optimum temperature of 21.1 to 26.6 C and to have all crustaceans of the same age and sex. Only 10 day old female crustaceans were used in this study. At this age they can readily be differentiated from the males, the females being twice as large as the males and less rapid swimmers.

Under the effects of various known concentrations of nicotine, the reactions of *Daphnia* were carefully studied so that they could be used as standards for comparative purposes. In concentrations of 1/100,000 and above the primary reaction is a period of paralysis—the time of onset being shorter the greater the concentration. In concentrations above 1/1,000 death quickly follows the stage of paralysis. Between nicotine concentrations of 1/100,000 and below alternate periods of convulsions and paralyzes are seen—the con-

vulsions dominating the picture. With decreasing concentration of the drug, the time required for the onset of the reactions becomes longer and less and less severe, so that at 1/2,000,000 periods of relative normalcy may occur. At concentrations of 1/10,000,000 and below the reactions are vague, ill defined and at most only suggestive of a nicotine effect. The term convulsion is applied to disorganized swimming movements of a twirling "loop the loop" type in a vertical plane. It is not a milk or urine effect. These movements were so characteristic of an early effect of nicotine that they were used as a criterion for the presence of nicotine in the milk and urine specimens. After the stage of paralysis and convulsions, swimming on the back occurs. Loop the loop movements have been observed also as an effect of other drugs, notably strychnine. With this drug these movements occur as part of the advanced symptoms and not, as with nicotine, as an early effect.

METHOD OF INVESTIGATION

Fifty-five white primiparas and multiparas between 18 and 36 years of age who were addicted to cigaret smoking were chosen after they had agreed to cooperate in this study. To be eligible, they had to have an apparently adequate supply of milk for their babies.

The lactating mothers were divided into three groups, according to the number of cigarettes smoked over a twelve hour period (7 a. m. to 7 p. m.). Group A consisted of occasional smokers (that is, women who smoked 1 to 4 cigarettes), group B of moderate smokers (5 to 10 cigarettes) and group C of heavy smokers (11 to 20 or more cigarettes).

Each mother was permitted to choose her own brand of cigaret, which in all cases was an American blend type. They were instructed to smoke completely each cigaret and, when possible, to inhale the smoke or at least blow it through their nostrils. This was advised to insure the absorption of nicotine. As a rule, the moderate and heavy smokers inhaled regularly, the light smokers less often.

Every effort was made to maintain an adequate supply of milk for the infants by a regular nursing schedule and, when necessary, by expressing the milk with an electric breast pump. After a sufficient quantity of milk was obtained by or for the infants, the residual milk in the breast was expressed and pooled over the twelve hour observation period. It was separated, however, into morning (7 a. m. to 1 p. m.) and afternoon (1 to 7 p. m.) specimens and kept refrigerated until tested for nicotine. The urine to be examined also was collected over this period, pooled, separated into morning and afternoon specimens and refrigerated until tested.

No mother in this study received any medication during the experimental period.

Practically all the mothers started to smoke within two days after their confinement. The specimens of milk for nicotine determination were obtained between the fourth and the ninth day post partum. Determinations could not be made on every specimen because the quantity of milk was insufficient for the tests. Determinations were not made on any specimen of milk or urine more than ten days old. The nicotine concentration was not affected by storage, for specimens of milk and urine known to be nicotine free to which definite amounts of nicotine were added gave accurate estimations after storage for two weeks.

PREPARATION OF THE MILK

The following method was used to decrease the turbidity and density of the milk so that the *Daphnia* crustaceans could be more easily observed.

Twenty-five cc of milk of each specimen was centrifuged for ten minutes to separate the fat. A pipet with a capillary tip was passed through the fat layer and the defatted milk drawn off. This milk was then recentrifuged for one hour to separate some of the proteins and solids as well as the remaining small amounts of fat. The milk was drawn off again, as described and the residue discarded. Oxygenation of the milk was then effected by bubbling air through it until a foam formed. This was necessary to provide a well aerated medium for the crustaceans. Nicotine determinations, on specimens of breast milk containing known amounts of nicotine and prepared in this manner, showed that nicotine was not lost by such treatment. Difficulty in observing *Daphnia* was infrequent. When it occurred, observation was facilitated by projecting a light through the milk specimen or by increasing the number of crustaceans in it.

PREPARATION OF THE URINE

The urine was filtered and a 1:10 dilution was made with the culture medium. This was the minimum dilution that was found from experiments to produce no effect on the animals during the period of time required for the estimation of the nicotine content. Undiluted normal urine exerted a toxic effect on the animals within five minutes and a lethal effect on them within twenty minutes.

ESTIMATION OF NICOTINE CONTENT

Fresh solutions of nicotine¹⁴ in *Daphnia* culture medium, ranging from 1:1,000,000 to 1:10,000,000 concentration for each estimation, were made from a stock solution of 1 per cent nicotine in distilled water. It was found that a stock solution of this strength did not lose any of its potency over a period of two months. No stock solution was used that was older. Ten of the crustaceans were placed in 50 cc clear glass jars, one jar for each of 2 prepared milk specimens and one jar for each of 5 preliminary control nicotine solutions. These were 1:10,000,000 (0.00001 per cent), 1:4,000,000 (0.000025 per cent), 1:2,000,000 (0.00005 per cent), 3:4,000,000 (0.000075 per cent) and 1:1,000,000 (0.0001 per cent). The small amount of culture medium which was transferred with the animals was removed with fine pipets, care being taken not to injure the animals. With the aid of assistants, and as quickly as possible, the milk specimens and each nicotine control solution were poured simultaneously into the jars.

Careful and continuous observations of the crustaceans in the milk and in the control solutions were recorded for the first five to seven minutes, a stop watch being used to record the time of the reactions. It is during the first five to seven minutes that the most striking nicotine effects can be seen and the time of their occurrence recorded most accurately.

Further observation of the crustaceans was continued, however, for fifteen to thirty minutes in order to record any unusual or latent effects of the nicotine. As the concentration of nicotine in the milk specimen did not always cause the same reactions in the animals as did the concentration of nicotine in a control solution, only an approximate reading at first was

obtained. The experiment was then repeated with other control solutions that gave, as near as possible, identical reactions. The specimens of milk that produced identical reactions in the animals as did a known control solution was considered to contain the same concentration of nicotine as the control.

The intensity of the reactions of the animals in the milk could not, however, be compared with those in the nicotine solutions, for it was found that, because of its density, the milk slightly impeded the movements of the animals. For this reason the time factor in these reactions was considered of utmost importance.

The amount of nicotine present in the specimen of urine was determined in a similar manner. The results were multiplied by 10 to correct for the dilution of the urine in preparing the specimen.

RESULTS

Nicotine was found present in every specimen of milk and urine obtained from mothers who smoked cigarettes. It was never found in any specimen obtained from mothers who did not smoke. While it would have been of great value and interest to determine the total concentration of nicotine in a twenty-four hour specimen of milk, this was not done because the

mothers would not permit their infants to be deprived of the milk necessary for this estimation. The estimations that were obtained, however, permit of significant deductions although it must be remembered that any bioassay cannot be compared to the accuracy of a chemical determination. A definite correlation between the number of cigarettes smoked and the quantity of nicotine secreted in the milk and urine was found (table 1).

In the group of occasional smokers (1 to 4 cigarettes), the average concentration of nicotine in 6 specimens of milk obtained in the morning period was 0.116 mg per liter and the average in 5 specimens obtained in the afternoon period was 0.16 mg per liter. In this group the average concentration of nicotine in 7 specimens of urine obtained in the morning period was 1.857 mg per liter and the average in 6 specimens obtained in the afternoon period was 2.75 mg per liter.

In the group of moderate smokers (5 to 10 cigarettes) the average concentration of nicotine in 27 specimens of milk obtained in the morning period was 0.225 mg per liter and the average of 23 specimens obtained in the afternoon period was 0.278 mg per liter. In this group the average concentration of nicotine in 32 specimens of urine obtained in the morning period was 2.828 mg per liter and the average in 31 specimens of urine obtained in the afternoon period was 3.645 mg per liter.

¹⁴ Nicotine was obtained from the Eastman Kodak Company, Rochester, N. Y.

Less than
† Milk very toxic to Daphnia accurate assay impossible

In the group of heavy smokers (11 to 20 and more cigarettes) the average concentration of nicotine in 11 specimens of milk obtained in the morning period was 0.445 mg per liter and the average of 11 specimens obtained in the afternoon period was 0.5 mg per liter. In this group the concentration of nicotine in 10 specimens of urine obtained in the morning period was 4.9 mg per liter and the average in 8 specimens obtained in the afternoon period was 6.62 mg per liter.

The constantly greater concentration of nicotine in the milk and urine obtained in the afternoon period was no doubt due to the continued excretion of some of the nicotine absorbed during the morning period in addition to that absorbed in the afternoon. This is in line with Finnucci's observation that the main excretion of nicotine appears in the milk and urine four to five hours after smoking. Approximately eleven to seventeen times as much nicotine was excreted in the urine as was excreted in the milk. The occasional lack of correlation between the number of cigarettes smoked and the quantity of nicotine in the milk and urine noted in table 2 can be explained by the varied methods in which cigarettes were smoked. In spite of the instructions to inhale or blow the smoke through the nostrils and to smoke each cigarette completely it was difficult for the mothers to alter their smoking methods. Some would take but an occasional draw and permit the cigarette to be for the most part consumed between the fingers or on an ash tray. Others discarded the cigarette when but one half to three fourths used while others would hold the cigarette constantly between the lips thereby inhaling as much smoke as possible, down to the last half inch. It is interesting therefore that even with these varied smoking methods there was obtained so close a correlation between the number of cigarettes smoked and the excretion of nicotine in the milk and urine.

EFFECT OF NICOTINE ON LACTATION

At the time of their discharge from the hospital which occurred about the tenth day post partum, 11 of the 55 mothers who smoked failed to have enough breast milk for the needs of their babies (table 3). Of the 8 occasional smokers (1 to 4 cigarettes), 2, or 25 per cent, failed. Of the 35 moderate smokers (5 to 10 cigarettes), 8, or 22.8 per cent, failed and of the 12 heavy smokers (11 to 20 or more cigarettes) only 1 or 8.3 per cent, had insufficient milk. The other 44 mothers in this study had sufficient milk to nurse their infants successfully during their stay in the hospital, after which time they passed from our supervision.

Although the number of cases studied is relatively small, it is nevertheless interesting that the largest percentage of women who failed to nurse their infants successfully occurred in the group of occasional smokers, while a lesser percentage occurred in the group of moderate smokers and the least percentage in the group of heavy smokers. There was no significant difference, however, between the number of failures in the various groups on application of the chi square test. If, as shown by Hatcher and Crosby, nicotine suppresses lactation, the largest number of failures should have occurred in the group of heavy smokers. It is our impression, however, that the number of mothers who smoked cigarettes and who failed to nurse their infants successfully was no greater than in the nonsmoking group at this hospital although no comparative statistical study was made.

EFFECT OF NICOTINE ON THE NURSING

In this study the keen interest and cooperation of the nursing personnel made it possible to obtain unusually careful and thorough records of the nurslings. Every untoward symptom was noted on the infants' charts even though it was but an occasional regurgitation of a mouthful of milk. As a consequence, an analysis of the records determined that only 2 of the 55 infants failed to regurgitate or vomit some time during their hospital stay (table 2).

The regurgitation and vomiting occurred, for the most part during the first four days of life, after which it gradually ceased. It was not severe, except in infant 1, in whom persistent vomiting occurred for the first three days and only occasional vomiting thereafter. This infant, who was entirely breast fed, was, nevertheless, 5 ounces (142 Gm) over its birth weight at the end of nine days.

In contrast to the records of the 55 infants of mothers who smoked cigarettes, the records, chosen at random of 55 infants of nonsmoking mothers failed to

TABLE 3—Effect of Cigarette Smoking on Lactation During Period of Study (Nine to Thirteen Days)

	Number	Adequate Lactation	Inadequate Lactation	Failures per Cent *
Occasional smokers (1-4 cigarettes)	8	6	2	25.0
Moderate smokers (5-10 cigarettes)	35	27	8	22.8
Heavy smokers (11-20+ cigarettes)	12	11	1	8.3

*There was no significant statistical difference between the number of failures in the various groups on application of the chi square test.

TABLE 4—Weight Gain and Loss of Nurslings at Time of Discharge (Ninth to Thirteenth Day)

	Number	Gain	Number	Loss	Same as Birth Weight
Occasional smokers (1-4 cigarettes)	4	5 oz	1	2 oz	1
Moderate smokers (5-10 cigarettes)	21	5.8 oz	5	3.6 oz	
	1	Premature			
		31 oz			
Heavy smokers (11-20+ cigarettes)	11	6 oz			

show any notation with regard to regurgitation and vomiting unless it was severe, because as stated by the nurse in charge, occasional regurgitation and vomiting was of such common occurrence that it was considered almost normal.

Regurgitation and vomiting is indeed a common occurrence during the newborn period and is due to so many causes that it is quite difficult always to determine the specific cause. Whether the nicotine in the milk caused the occasional regurgitation and vomiting in the nurslings of smoking mothers is extremely doubtful, for in all the infants it had practically ceased while they still were ingesting milk containing nicotine. It is of particular interest that 1 of the 2 infants who did not regurgitate or vomit (case 54) was the offspring of a mother who smoked 18 cigarettes over a twelve hour period and whose milk contained the high average nicotine concentration of 0.75 mg per liter.

The bowel movements of all the nurslings of mothers who smoked cigarettes were carefully examined for any abnormalities and a record was kept of the number of them. In no instance was either an abnormal or an excessive number of bowel movements observed. Toxic effects from nicotine such as irritability

sive crying, lassitude and pallor were never noticed, in fact, it was the unanimous opinion of the nurses caring for these infants that they were as normal as the infants of nonsmoking mothers

The gains and losses in weight of the nurslings of mothers who smoke cigarettes are perhaps the most important criterion on which to base the effect of the nicotine in the milk (table 4). Of the 55 nurslings, 44 were solely breast fed and 11 received complementary feeding of cow's milk.

Of the 44 infants, 37 were above, 6 were below and 1 was at its birth weight at the time of discharge from the hospital, which occurred between nine and thirteen days after birth.

Of the 6 nurslings of mothers in the group of occasional smokers, 4 had gained an average of 5 ounces (142 Gm), 1 had lost 2 ounces (57 Gm) and 1 was at its birth weight at the time of discharge.

Of the 27 nurslings of mothers in the group of moderate smokers, 21 had gained an average of 5½ ounces (162 Gm), 1 premature infant had gained the remarkable total of 1 pound and 15 ounces (879 Gm) and 5 had lost an average of 3½ ounces (102 Gm) at the time of discharge.

Of the 11 nurslings of mothers in the group of heavy smokers, all had gained an average of 6 ounces (170 Gm).

TABLE 5—Average Gain and Loss of Nurslings on Complementary Feedings at Time of Discharge (Ninth to Thirteenth Day)

Number	Gain	Number	Loss
9	4 7 oz	2	2 9 oz

Of the 11 infants who were on complementary feedings (table 5), 9 had gained an average of 4⅞ ounces (133 Gm) and 2 had lost an average of 2½ ounces (62 Gm).

Without doubt this analysis indicates that nicotine has little, if any, effect on the ability of an infant to gain weight. It is interesting to note not only that all the nurslings of mothers in the group of heavy smokers gained but that their average gain was slightly more than the nurslings of mothers in the groups of occasional and moderate smokers.

COMMENT

The ease with which *Daphnia* could be observed in the milk and urine and compared with the control solutions of nicotine permitted accurate estimations.¹⁵

Our estimations, however, yielded much higher figures than those of Hatcher and Crosby and of Emanuel. The former, using the frog method, found less than 0.015 mg of nicotine in the milk after smoking, and the latter, using leech segments, found a maximum of 0.03 mg of nicotine per liter of milk after smoking 7 to 15 cigarettes.

Whether our average figures, which ranged from 0.116 mg to 0.5 mg of nicotine per liter of milk, depending on the number of cigarettes smoked, were due to the *Daphnia* method of bioassay is difficult to say, as comparative assays with other biologic methods were not made. Our figures certainly would have been lower had the night specimens, which contained very little nicotine, been pooled with those of the day specimens, when practically all of the smoking was done.

¹⁵ Viehoveer, Arno. *Daphnia the Biologic Reagent*. J Am Pharm A 25: 1112-1117 (Dec) 1936.

The quantity of nicotine that would produce toxic effects in an infant is not known. Schroff, according to Emanuel, demonstrated on himself that the first toxic symptoms appear after the intake of 1 to 4 mg of nicotine. A comparable intake for an infant of 6 to 7 pounds (2,722 to 3,175 Gm) would therefore be in the neighborhood of 0.05 to 0.2 mg. If the infants in our study could, theoretically, have ingested at one time an entire liter of milk containing the concentration of nicotine found present in the specimens assayed, they would have obtained considerably more than the toxic dose of Schroff. They obtained, however, but 200 to 500 cc of milk during a twenty-four hour period. Consequently, the actual amounts of nicotine ingested at a feeding were, in practically all, below the toxic threshold.

The absence of any demonstrable deleterious effect of nicotine on lactation and on the infants may be due also to the development of a tolerance to the drug. The development of tolerance to nicotine by smokers is well known. As all the mothers had smoked before, during and after their pregnancies, they unquestionably had a high tolerance to nicotine. The infants, exposed to the nicotine in their mother's blood while in utero, likewise had the opportunity to develop a tolerance to it—practically from the time that they were conceived. Behrend and Thienes¹⁶ have shown experimentally that tolerance to nicotine can develop. They demonstrated that tolerance to the minimal effective dose and minimal convulsive dose can develop in young rats and that adult rats do not develop a tolerance to the fatal dose of nicotine.

The physiologic process involved in the development of nicotine tolerance was shown by Werle,¹⁷ who found that the unexcreted portion of nicotine in the body is destroyed chiefly by the liver and that the kidneys and lungs as well as the liver of rabbits contain an enzymic system capable of detoxifying nicotine.

Dixon and Lee¹⁸ also found that the livers of habituated animals destroyed nicotine somewhat more rapidly than those of the nonhabituated ones.

The factor of tolerance to nicotine must therefore be taken into consideration before the effect of this drug on man and animals can be evaluated properly.

CONCLUSIONS

- 1 Nicotine was excreted in the milk and urine of all the mothers who smoked cigarettes.
- 2 Much larger quantities of nicotine were excreted in the urine than in the milk.
- 3 There was a definite correlation between the quantity of nicotine excreted in the milk and urine and the number of cigarettes smoked.
- 4 Lactation was little, if at all, affected by the smoking of cigarettes.
- 5 The nurslings were apparently unaffected by the quantity of nicotine that they ingested with the milk.
- 6 A tolerance to nicotine may be a factor which prevents this toxic drug from affecting the infants and the lactating ability of the mothers.

ABSTRACT OF DISCUSSION

DR WILLIAM BIRNOW THOMPSON, Los Angeles Dr Perlman and his co workers have carefully assayed the nicotine content of the breast milk of 55 mothers who continued their smoking habits. It is highly significant that they detected nicotine in every instance in which the milk came from a woman who smoked, and that they failed to obtain a positive reaction when smoking had not been a factor. It is likewise significant that the values determined increased in direct proportion to the amount of smoking. It is evident that these values are small, and probably below the threshold of toxic effect on even immature infants. At least it is true that no toxic reactions were observed. Within the last few years there has been vast improvement in biologic assays. The detection of nicotine, in particular, is much more delicate with the use of *Daphnia* than with the use of frogs or leeches, and the estimation of amounts is less susceptible to experimental error. While one cannot assume that the skim milk would contain less nicotine than the cream, this probably is the case, since nicotine is more soluble in oil than in water. If that should be true, these reported amounts of nicotine would be increased somewhat. In this failure to utilize the entire milk output lies the only point wherein my own report may be deemed superior. The most startling feature of this study was that 44 of 55 mothers left the hospital with their babies entirely on breast feeding. I was so impressed that I went back over the records of 150 deliveries in which the mothers had been in for their six weeks check-ups, divided equally between primiparas and multiparas. On discharge from the hospital at twelve to fourteen days there were 16 primiparas and 6 multiparas feeding their babies, and 22 primiparas and 26 multiparas using complementary feedings. At six weeks even these figures had shrunk to 9 primiparas and 9 multiparas with an adequate supply, and 5 primiparas and 7 multiparas with partial feeding. At six weeks, then, only 30 to 20 per cent of these mothers were making any effort at lactation. Of this group, among the primiparas there were 33 who were nonsmokers at the time their histories were taken, although 7 had recently stopped because of nausea. Eight were light smokers, 7 were moderate and 27 were heavy smokers. The impressions of the earlier investigators, including myself, are confirmed by Perlman and his co workers in that the amounts of nicotine thus excreted are so infinitesimal that they cannot logically be the basis for the usual and average disturbances of the infant digestive tract. While the minute quantities present in the milk of even a heavy smoker cannot be shown to have any deleterious effect, certainly it cannot be proved to be beneficial.

DR A M DANNENBERG, Philadelphia I am glad that Dr Thompson brought up the question of the fat in the milk. In our study it was necessary for us to remove the fat in order that the *daphnia* would have a less dense medium in which to swim. We tried many ways to prepare the milk. It was filtered through felt, silica gel, glass wool and other filters but, unfortunately, these methods were not so satisfactory as the method adopted for our study. It was found through experiment that the nicotine concentration in breast milk was not altered by removing the cream. Lest some may think that we have an unusual group of lactating mothers in our hospital, I wish to state that this study was carried out over a period of three years, and it took all of that time to obtain 55 mothers with an apparent adequate supply of milk to cooperate in this study.

What Happens in Shock?—When a person passes into a condition of shock the sequence of events has been as follows: first, the trapping of a certain volume of blood in the capillary areas, nervous influence, cold, and toxemia from bruised and damaged muscle being the principal influences in producing the change, second, a fall in blood pressure as the result of the reduction in blood volume, third, deficient oxidation of tissue in the area where capillary stasis is occurring, and, fourth, a condition of acidosis resulting from a fall in the alkali reserve of the tissue and a corresponding rise in the carbon dioxide content of the blood plasma.—Fraser, Sir John, Shock and Hemorrhage, from War and the Doctor, edited by J M Mackintosh, M D, Baltimore, William Wood & Co., 1942

A PREPARATION FROM SPOILED
SWEET CLOVER

[3,3'-METHYLENE-BIS-(4-HYDROXYCOUMARIN)] WHICH PRO-
LONGS COAGULATION AND PROTHROMBIN TIME OF
THE BLOOD A CLINICAL STUDY

EDGAR V ALLEN, M D
NELSON W BARKER, M D
AND
JOHN M WAUGH, M D
ROCHESTER, MINN

It has been known for many years by veterinarians and cattle raisers that cattle fairly frequently and for no apparent reason bleed considerably and perhaps fatally. Studies of this condition were made originally and independently in 1921 by Schofield¹ in Canada and by Roderick² in this country. They determined that this hemorrhagic disease arises from eating improperly cured hay or silage made from the common sweet clovers. It was recognized early that if the hemorrhagic manifestations had not proceeded too far the hemorrhage could be controlled by withdrawal of the spoiled hay from the diet or by the injection of freshly drawn blood serum of healthy animals.³ At first it was thought that the liver was damaged by the ingested spoiled hay, but this could not be confirmed by Roderick. However, he noted that the delayed coagulability of the blood involved a reduction in the prothrombin content of the blood and that this diminution paralleled the delay in the coagulation time.⁴ This observation was confirmed later by Quick.⁵ Roderick did not find any significant changes in the urine of the diseased cattle. The chemical constituents of the blood were found to be normal.⁶

Since 1934 Prof Karl Paul Link and his associates of the Wisconsin Agricultural Experiment Station at the University of Wisconsin have been attempting to obtain the active hemorrhagic agent from spoiled clover. The story of this work has been unfolded in a series of brilliant reports,⁷ finally crowned with the reports in

From the Division of Medicine (Drs Allen and Barker) and the Division of Surgery (Dr Waugh) the Mayo Clinic.

Because of lack of space this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Drs E A Hines Jr and W F Kvale gave clinical help. Miss Margaret Hurn performed numerous prothrombin time tests and members of the surgical and medical staffs of the Mayo Clinic cooperated in this study.

March and April of 1941 of the isolation and synthesis of the hemorrhagic agent.⁸ Additional studies were reported in 1942.⁹

Professor Link and his associates have been most generous in replying to our inquiries and in allowing us to study some of their work before publication. In April 1941 they sent us promptly some of the synthetic compound. We believed that the preparation might be used advantageously in place of heparin, which we and others have used clinically with benefit. The disadvantages of heparin are (1) the cost of its use (about \$10 daily), (2) the need for continuous intravenous infusion or repeated intravenous injection and (3) the difficulty of maintaining a constant effect on coagulation time. A study of the effect of dicoumarin on dogs was begun about the middle of April 1941, and on May 9, 1941 we first administered the compound to a human being after it had been determined that the amounts administered in all probability would not cause any untoward effects. After some preliminary study an intensive program was begun to determine whether or not the preparation would prevent intravascular thrombosis in patients.

The hemorrhagic agent employed was dicoumarin [3,3'-methylene-bis-(4-hydroxycoumarin)] prepared by the method described by Campbell and Link. The compound is white, crystalline and only slightly soluble in water, but it is readily soluble in alkaline solutions. The drug was supplied to us by Abbott Laboratories and was administered by mouth in standard gelatin capsules, each of which contains 100 mg.

Two of our associates and one of us (Allen) first published the results of clinical studies on this preparation¹⁰ in June 1941.¹¹ A report of further experiences by two of us (Barker and Allen), Butt and Bollman was given before the Central Society for Clinical Research in Chicago on Nov 7, 1941. An abstract of this report was published in March.¹² The report of Bingham, Meyer and Pohle, published in October 1941, indicates that Link had given them dicoumarin for a study of its pharmacologic and clinical properties in September 1940.¹³ An abstract of a second report by these authors^{13a} was given before the Central Society

for Clinical Research on November 7, and a subsequent report has been made by Meyer, Bingham and Axelrod.¹⁴ Other reports on the effects of dicoumarin on human beings have been made by Townsend and Mills,¹⁵ Stats and Bullowa,^{16a} and Prandoni and Wright.^{17b}

In our study the prothrombin time for the blood of patients was determined by Magath's¹⁰ modification of the method devised by Quick and his associates.¹⁷ In some instances the coagulation time of human blood was measured by the method described by Murray and Jones,¹⁸ and in others the method of Lee and White¹⁹ was employed. Other tests were carried out in the usual manner.

EFFECTS OF DICOUMARIN

The effect of dicoumarin seems to be on prothrombin only. The prolongation of prothrombin time indicates the destruction of prothrombin or the suppression of its action or inhibition of the formation of prothrombin. Something in the body is necessary for the action of dicoumarin because if dicoumarin is added to drawn blood the prothrombin time is not influenced.¹³ Coagulation time may be prolonged as a result of adminis-

TABLE 1—Effect of Postoperative Administration of Dicoumarin on the Blood

Cases	Prothrombin Time Seconds	Bleeding Time Minutes	Clot Retraction	Sedimentation Rate, mm in First Hour	Platelets per Cubic Millimeter of Blood
1	42	2½	None in 7 hours		87,000

10	33	5	Complete in 1½ hours	69	202,000

tration of dicoumarin but determination of it is not a satisfactory method of measuring the activity of dicoumarin.

The studies of Bollman on animals of Bingham, Meyer and Pohle on human beings and our own studies²⁰ indicate that hepatic function, the composition of urine, the value for blood sugar, the erythrocyte and leukocyte counts, the concentration of bilirubin and calcium in the serum, the value for the nonprotein nitrogen in the blood, the icteric index and the fragility of the erythrocytes and blood platelets are uninfluenced when dicoumarin is administered. As a part of our present

9 The name of this hemorrhagic agent as published in the title is too cumbersome for ordinary use. We do not like the term "hemorrhagic agent" for common usage because it may be used repeatedly without inducing hemorrhage. We use the name dicoumarin recognizing that the dicoumarin is a family name applying to related compounds and that the hemorrhagic agent is a dicoumarin. Hence in this paper the term dicoumarin applies to the hemorrhagic agent correctly described in the title of this presentation. More recently the term dicoumarol has been advocated and it is probable that this name will be adopted universally.

study we have determined that the bleeding time is not influenced by dicoumarin is used clinically. The sedimentation rate of erythrocytes is almost routinely increased. There is definite retardation of clot retraction in many instances, but this is an inconstant finding (table 1). In the 10 cases in which the clot retraction and sedimentation rates were studied, dicoumarin was administered prophylactically after operation.

Bingham, Meyer and Pohle noted only moderate hydropic degeneration of the liver when dogs were given fatal doses of dicoumarin. Bollman has given dicoumarin repeatedly and for long periods to animals. According to him, hemorrhage occurs when large doses are given and when the prothrombin in the blood is greatly depleted, but the structures of the liver, kidneys and other vital structures are unchanged unless hemorrhage into them has occurred. Bingham and his associates reported that "Therapeutic and fatal doses of this material given to dogs did not produce significant pathologic changes in the liver or other parenchymatous organs but did, in many instances, produce capillary arteriolar and venule dilatations." Rose, Harris and Chen^{20a} observed that fatal doses of dicoumarin produced hemorrhage in various organs and tissues and also caused pulmonary edema. They found central necrosis of the liver in about half of the rats used in their study, but this was observed only occasionally among rabbits, mice and dogs that were used. In 4 cases we did not observe any significant alteration of hepatic function or in the concentration of serum bilirubin during or after administration of dicoumarin for short periods of time (one to two weeks).¹¹ Naturally one cannot conclude from short term studies such as this that dicoumarin is not harmful; similar results should be noted after administration for long periods of time before such conclusions can be drawn. In this connection, the studies of Link reported in conversation are interesting and valuable. Animals given dicoumarin or fed spoiled sweet clover hay repeatedly over a period of six or seven years so that the prothrombin time of their blood was increased (dicoumarin effect) about half of the time were well at the end of this time. They died of old age, as did those animals of similar age which had not received dicoumarin, and at necropsy there was no gross evidence of disease. The evidence from all these studies seems quite conclusive; dicoumarin inhibits the action of prothrombin by destroying it or by inhibiting its production. Secondary effects are interference with normal clot retraction and increased rate of sedimentation of erythrocytes. If enough dicoumarin is given, coagulation time is prolonged and bleeding may occur. In this connection, as we will emphasize later (except in cases of subacute bacterial endocarditis), the danger of bleeding is minimal unless the prothrombin time is greatly prolonged. Patients are ordinarily unaware of any effects of the drug. Urticaria and headache resulted in 1 case.

ROUTES OF ADMINISTRATION THE LATENT PERIOD

We have given dicoumarin orally to all our patients. Under these circumstances there is a lag or latent period between the administration and the appearance of the effect. This lag is usually twenty-four to forty-eight hours. The disodium salt has been given intravenously by Bingham and his associates, who expressed the opinion that 4 to 5 mg for each kilogram of body

weight may be given intravenously to patients with safety.¹³ Link has informed us in conversation that there is a latent period between the time of intravenous injection and the action on prothrombin time which is about the same as when dicoumarin is administered orally. The only advantages of intravenous administration, therefore, would seem to be (1) prevention of irregular effect owing to irregular absorption from the gastrointestinal tract and (2) use in instances in which the oral route cannot be used, as for example after operations on the gastrointestinal tract. At present a stable preparation for intravenous injection is not available. The effectiveness of the drug when given rectally and by injection into the skin is being studied.

DICOUMARIN SHOULD BE ADMINISTERED ONLY IF THE PROTHROMBIN TIME CAN BE DETERMINED REPEATEDLY

It is well to emphasize here that dicoumarin is a hemorrhagic agent which may produce dangerous hemorrhage unless its administration is controlled rigidly. The amount of drug administered must depend on the prothrombin time. Hence at present, dicoumarin should not be given unless the prothrombin time can be determined. It is our opinion that the Quick method, as modified by Magath, is satisfactory. With

Chart 2—Strong response by prothrombin time to a relatively small amount of dicoumarin administered orally

this method the prothrombin time can be determined accurately by experienced technicians after a little practice.

At present, determinations of the prothrombin time are made on the blood of each patient each day, but, as experience is gained, we believe that administration may be successfully controlled in most cases if such studies are performed every two or three days. In the future a pattern of reaction to a specified amount of dicoumarin may be established, particularly if it is given intravenously. Under these circumstances determinations of the prothrombin time might be needed rarely. At present, however, we cannot recommend departure from the plan of determining the prothrombin time daily when dicoumarin is being administered.

METHOD OF ADMINISTRATION OF DICOUMARIN

We have given our patients single doses of 200 or 300 mg of dicoumarin on the first day and 200 mg on the second day. Subsequent to the first and second days decision relative to administration of dicoumarin is deferred until the prothrombin time of the blood drawn on that day is known. In our experience it is desirable to administer dicoumarin so as to keep the prothrombin time between thirty-five and sixty seconds. Because of apparent irregularities of absorption and differences in the sensitivity in different cases, no ratio has been established between the body weight

^{20a} Rose C L, Harris P N and Chen K K. Toxicity of 3,3-Methylene Bis (4-Hydroxycoumarin). *Proc Soc Exper Biol & Med* 50: 228-232 (June) 1942.

every six hours. Usually, such injections need to be continued for thirty-six to forty-eight hours, at which time dicoumarin has become effective.

THE EVIDENCE THAT DICOUMARIN LESSENS THE TENDENCY TO INTRAVASCULAR COAGULATION OF BLOOD

Clinical studies which will be reported later in this paper indicate that when the prothrombin time is increased by means of administration of dicoumarin, intravascular thrombosis does not ordinarily occur. Studies by Bollman and Preston²³ on animals indicate that this is true. Their studies indicate that glass cannulas interposed between two ends of an artery seldom are occluded by thrombi when animals have received dicoumarin. Venous thrombi which occurred

particularly dangerous in subacute bacterial endocarditis. This probably results from the increased tendency of patients with subacute bacterial endocarditis to bleed from kidneys or into the brain even when dicoumarin is not used. The reported experiences with heparin indicates that there is also danger from using it in subacute bacterial endocarditis. The effect of dicoumarin on prothrombin time is excessive in cases of renal insufficiency or in those in which adequate amounts of urine are not excreted. It should be used very cautiously or not at all under these circumstances. Bollman and Preston's experiments indicate that renal failure enhances the effect of heparin tremendously. Naturally it should not be used in cases in which the prothrombin time is already prolonged (vitamin K deficiency).

TABLE 2—Effect of Dicoumarin Occurrence of Venous and Arterial Thrombosis, Pulmonary Embolism and Bleeding

Reason for Anticoagulant Therapy	Cases	Successful Elevation of Prothrombin Time (>7 Seconds)	Pulmonary Embolism or Infarction While Prothrombin Time Was Elevated	Arterial or Venous Thrombosis While Prothrombin Time Was Elevated	Bleeding		Deaths
					Major Blood Transfusion Required	Minor

* In 1 case thrombophlebitis developed when prothrombin time was 76 seconds. In 1 case embolism developed when prothrombin time was 25 seconds. Treatment with dicoumarin was considered inadequate in these cases.

regularly under a set of "normal" circumstances seldom occurred in animals that had received dicoumarin. In their experience, dicoumarin could be used in the laboratory to replace heparin in experiments in which intravascular coagulation of blood was to be avoided. By means of experiments on dogs, Dale and Jaques^{23a} showed that the administration of dicoumarin decreases considerably the tendency to thrombosis in veins which have been crushed on a linen thread and also in glass cells inserted between the carotid artery and the jugular vein. Richards and Cortell^{23b} have shown that after administration of dicoumarin there is pronounced inhibition of the formation of thrombi in veins into which a sclerosing solution, ethanolanine oleate, has been injected.

CONTRAINDICATIONS TO THE USE OF DICOUMARIN

Dicoumarin should not be used for patients who are bleeding. Our experience indicates that its use is par-

RESULTS OF CLINICAL STUDIES

We have administered dicoumarin in 374 cases. Six of these cases were reported previously.¹¹ The indications for the use of the drug in the remaining 368 cases are shown in table 2. In these cases, dicoumarin was given in an effort to prevent arterial or venous thrombosis and pulmonary embolism or to prevent extension of intravascular thrombosis. Since we feel that an embolus is always a very recent thrombus or a portion of a very recent thrombus, prevention of extension of thrombosis is important. In the cases of postoperative pulmonary embolism, infarction and postoperative thrombophlebitis, the administration of the dicoumarin was begun as soon as the clinical diagnosis was made. In a few cases heparin was used until dicoumarin became effective. In cases in which thrombophlebitis or pulmonary embolism had complicated a previous operation and in cases in which abdominal hysterectomy or other operations were performed on patients who had not had thrombophlebitis or embolism, administration of dicoumarin was begun approximately twenty-four hours after the operation was performed. Slight elevation of the prothrombin time may be sufficient to

²³ Bollman, J. L., and Preston, F. W. Unpublished data.

prevent thrombosis, but it is probable that a definite elevation of the prothrombin time is necessary in many cases. Hence we desire to keep the prothrombin time between 35 and 60 seconds during the "danger period" in preventing intravascular thrombosis. Pulmonary intarction developed in 1 case in which the prothrombin time was 26 seconds (normal is 19 to 22 seconds) and thrombophlebitis developed in 1 case in which the prothrombin time was 35 seconds and in another case in which it was 45 seconds. However, these are the only 3 instances of clinical thrombosis which developed in the entire 374 cases during the time the prothrombin times were elevated. In our experience, bleeding of moderate or severe degree occurred only when the prothrombin time was above 60 seconds except in 2 cases.

The reasons for feeling that elevation of the prothrombin time as a result of administration of dicoumarin prevents thrombosis are summarized in table 3. In a statistical study of postoperative venous thrombosis

cases in which thrombophlebitis or embolism complicated previous operations and the 124 cases in which abdominal hysterectomy was performed are too small a series to warrant conclusions as to whether elevation of the prothrombin time by administration of dicoumarin really prevents thrombosis or not, although, as noted in the table, some instances of thrombophlebitis or pulmonary embolism could have been expected in these groups from a statistical standpoint.²³ In cases in which the drug was administered after operation, both those in which either venous thrombosis or embolism occurred and those in which neither thrombosis nor embolism occurred, the prothrombin time was kept elevated until the patient was ambulatory, that is, for seven to twenty-one days. In several of the cases of peripheral vascular disease, dicoumarin was given for a considerably longer period (table 4 and chart 6).

Because of the fact that bleeding occurs in animals poisoned with spoiled sweet clover and occasionally

TABLE 4—Effect of Dicoumarin in Cases of Peripheral Vascular Disease

Case	Disease	Total Dose of Dicoumarin Mg	Duration of Treatment with Dicoumarin Days	Results
11	Diabetes mellitus sudden arterial thrombosis of foot cellulitis	700	11	Effect stopped by blood transfusion because of emergency amputation prolonged bleeding from stump

and pulmonary embolism, Barker, Nygaard, Walters and Priestley²⁴ found that in cases of pulmonary embolism in which patients survived the chance of subsequent development of thrombophlebitis or pulmonary embolism during the next few weeks was 44 per cent, that the chance of subsequent development of embolism was 30 per cent and that the chance of the subsequent development of fatal embolism was 18.5 per cent. Although our series of 69 cases of postoperative pulmonary embolism in which dicoumarin produced adequate elevation of the prothrombin time is small, it is probably statistically significant that subsequent thrombosis developed in only 1 of these cases when the prothrombin time was elevated only to 26 seconds and that embolism did not develop in this group except in 1 case in which the prothrombin time was elevated only to 25 seconds. As stated previously, we feel that this effect of the dicoumarin is inadequate. The 45 cases of postoperative thrombophlebitis, 13

in laboratory animals that have received large doses of dicoumarin over long periods of time and because of the known tendency of patients who have elevation of prothrombin time as a result of hepatic disease to bleed, our patients who received dicoumarin as anticoagulant therapy have been observed carefully for any evidence of hemorrhage even of minimal degree. Slight bleeding from the wound may occur occasionally after any operation, particularly if it involves the vagina. Hence, some of the bleeding that we have noted might have occurred anyway and may not have had anything to do with the administration of dicoumarin. We encountered bleeding in 31 cases, which are included in table 5. The bleeding was of a slight degree in 17 cases, of a moderate degree in 9 cases and of a severe degree in 5 cases. The bleeding was from the operative site in 24 cases, ecchymosis of the skin of the thigh developed in 2 cases, hematuria developed in 4 cases and nasal bleeding developed in 2 cases. A nasal tube had been used in 1 of these cases. Cerebral bleeding occurred in 3 cases, in 1 of these cases extensive hemorrhage occurred in many organs. In 3 cases the bleeding from the site of operation was severe and in 1 case it was

24 Barker W, Nygaard K, Walters, Waltman and Priestley J T. A Statistical Study of Postoperative Venous Thrombosis and Pulmonary Embolism. III. Time of Occurrence During Postoperative Period. Proc Staff Meet. Mayo Clin 16: 17-21 (Jan 8) 1941.

fatal. As previously stated, it is doubtful whether dicoumarin was an etiologic factor in this case. Two other patients died, apparently as a result of hemorrhage. Both of these had subacute bacterial endocarditis. In 1 of these cases the clinical picture of cerebral hemorrhage developed. Necropsy was not done. A cerebral hemorrhage may occur spontaneously in cases of subacute bacterial endocarditis, but we must assume that elevation of the prothrombin time could have favored such a lesion. In another case of subacute bacterial endocarditis, in which sulfadiazine also was administered, urina developed suddenly, and forty-eight hours later numerous ecchymoses developed in the skin and oral mucosa. Coma and death ensued. Necropsy revealed extensive hemorrhages in many organs and tissues. We feel that patients with subacute bacterial endocarditis have an increased tendency to bleed as a result of the disease and hence have a great deal more tendency to bleed when the prothrombin time is elevated than do patients in the other clinical groups that we have observed. There had not been any evidence of thrombosis or embolism in any of the 3 cases in which death was due to hemorrhage.

We have not found a correlation between the tendency to bleed and the exact levels of the prothrombin time, as we have seen prothrombin times of two or three minutes without any evidence of hemorrhage.

CONCLUSIONS

1 Dicoumarin when administered orally prolongs the prothrombin time, impairs clot retraction and increases the sedimentation rate of erythrocytes. Large amounts prolong the coagulation time. Hemorrhage may occur when dicoumarin has greatly prolonged the prothrombin time. The drug seems essentially harmless otherwise.

2 Dicoumarin should be administered only when its effect can be determined by repeated calculations of the prothrombin time.

3 The response of the prothrombin time of different patients is variable. In general, larger doses produce greater prolongation of prothrombin time than do smaller ones, and the effect endures longer.

4 A plan of administering 300 mg. on the first day, 200 mg. on the second day and 200 mg. on each day after the second on which the prothrombin time is less than 35 seconds has been used by us.

5 After administration of the first dose from twenty-four to forty-eight hours elapse before an effect on prothrombin time is noted. After discontinuation of administration, prothrombin time may be prolonged from two days to two or three weeks, depending on the amount given.

6 Heparin and dicoumarin may be administered together when both quick and prolonged action are desired. The use of heparin is discontinued when the prothrombin time has been satisfactorily prolonged by dicoumarin.

7 Synthetic vitamin K has little or no effect on prolongation of prothrombin time resulting from dicoumarin. Transfusion of fresh blood will reduce for variable periods the prothrombin time which has been increased by dicoumarin.

8 Clinical and experimental studies strongly suggest the value of administration of dicoumarin in preventing intravascular thrombosis.

9 The danger of hemorrhage from administration of dicoumarin serves as a constant emphasis for care in its use.

THE DICOUMARIN 3,3'-METHYLENE-BIS-(4-HYDROXYCOUMARIN)

ITS PHARMACOLOGIC AND THERAPEUTIC ACTION IN MAN

IRVING S. WRIGHT, M.D.
AND

ANDREW PRANDONI, M.D.
NEW YORK

One of the most interesting and challenging developments in the field of the biologic sciences in recent years has been the recognition, isolation and, finally, synthesis of the substance causing hemorrhagic sweet clover disease in cattle, the dicoumarin 3,3'-methylene-bis-(4-hydroxycoumarin). We must give full credit for this contribution to two keen students of veterinary medicine, Schofield¹ and Roderick,² and to an outstanding agricultural chemist, Karl Paul Link. Schofield in Canada and Roderick at the North Dakota Agricultural Experimental Station studied and quite accurately analyzed the factors responsible for this phenomenon in cattle and rabbits. They pointed out that, whereas normal sweet clover silage produced no damage, spoiled sweet clover resulted in hemorrhagic tendencies and often in death. In 1934 Prof. Karl Paul Link and his associates at the Wisconsin Agricultural Experimental station of the University of Wisconsin undertook the

The dicoumarin 3,3'-methylene bis (4-hydroxycoumarin)

task of identifying the hemorrhagic factor in spoiled sweet clover.

This marked the beginning of a series of careful investigations, brought to fruition seven years later with the discovery that coumarin, the aromatic bitter tasting substance in sweet clover, is the compound that undergoes change when the hemorrhagic agent is formed in sweet clover spoilage.

In a series of brilliant reports³ published, beginning in 1940, Link and his co-workers established that the hemorrhagic agent was a dicoumarin and succeeded in isolating, crystallizing and synthesizing the biologically active substance. More than one hundred and fifty compounds, either analogues or related in structure, have been prepared, of which forty have been shown to have prothrombin reducing properties. This discussion was conclusively demonstrated by Stahmann, Hueb-

ner and Link⁷ to be the dicoumarin 3,3'-methylene-bis-(4-hydroxycoumarin)

It was obvious that the isolation and synthesis of this dicoumarin, which could be prepared in quantity, would prove of interest to workers in the field of either vascular or blood diseases, and through the courtesy of Dr Link several clinical groups have been studying its action in man during the past two years. Meyer, Bingham and Pohle¹⁰ presented the first report on the action of this dicoumarin in man on Feb. 27, 1941. In June, Butt, Allen and Bollman¹¹ published a preliminary study of its use in dogs and a series of 6 in human beings. In October 1941 we presented our preliminary observations on the use of this substance¹² in a series of 20 human subjects.¹³ Since that time further progress reports have been presented by each of these groups. Each group presented a report before the American Society for Clinical Investigation on May 4, 1942. In general, the observations of these three groups have been similar. All have found that in man, as in

Chart 1 (case 4) — Response of coagulation and prothrombin times to administration of dicoumarin. The patient aged 37 weighing 135 pounds had a diagnosis of thromboangitis obliterans.

lower animals, the administration of dicoumarin results in a prolongation in the prothrombin time and a delay in the coagulation of the blood. It was determined that there is a lag of from twenty-four to seventy-two hours before the action of the drug is measurable. Bingham, Meyer and Pohle¹⁴ showed that this was true whether the substance was given orally or intravenously. All reported that fresh transfusions of serum or whole blood will cause prompt lowering of the prothrombin and coagulation times but that in some

instances this effect is not sustained, thus necessitating several transfusions. We found that bank blood older than 96 hours had no effect, probably owing to loss in prothrombin activity. Each group of investigators was disappointed in the effect of vitamin K. In the dosage usually effectively employed in cases presenting prothrombin deficiency vitamin K consistently failed to produce any response toward normal in prothrombin deficiency due to dicoumarin.

In October 1941 we reported for the first time in man a hemorrhagic syndrome following the administration of the dicoumarin 3,3'-methylene-bis-(4-hydroxycoumarin).¹³ This was essentially the same in its manifestations as the syndrome of hemorrhagic sweet clover disease. In 8 of our first 20 patients hemorrhagic manifestations were noted. A summary of these case histories will be found in table 1. There was a wide unexplained variation in the hemorrhagic response in different individuals. As noted in table 2, the dosage was comparable in the hemorrhagic and the nonhemorrhagic group in regard to both magnitude and duration of therapy. For example, patient 34¹² in our series received a total of 81 Gm of the drug, or 987 mg per kilogram of body weight—the largest dose given without any toxic manifestations. Other patients received 3.6 Gm, 3.4 Gm, 3 Gm and similar doses without ill effects. The following case reports are typical of the phenomenon as it occurs in man.

CASE 4—A man aged 37 weighing 135 pounds (61.2 Kg), with a diagnosis of thromboangitis obliterans and osteomyelitis of the left second toe, after a control period of seventy-two hours had a normal prothrombin time of 20 to 27 seconds and a coagulation time of 6 to 8 minutes. He received 100 mg of dicoumarin every twenty-four hours. The first significant elevation in prothrombin time occurred seven days after inception of therapy, at which time the prothrombin time rose to 28 seconds. The coagulation time rose to 10 to 5 minutes on the same day. The total dose until then was 700 mg. The dose was then doubled (200 mg every twenty-four hours). Prothrombin and coagulation times continued to increase during the subsequent period, the prothrombin time attaining 34 seconds and the coagulation time 10 minutes on the thirteenth day.

Dicoumarin was discontinued at this time because the patient's temperature had risen to 101 F. The pulse rate was 110 and the respiratory rate 24. The total dose of dicoumarin was 1,700 mg. Purpura appeared in the skin of the left leg and foot. The gums bled profusely. The patient complained of lumbar pain. A capillary fragility test (15 minutes midway between systolic and diastolic pressure) revealed ten petechiae (normal). The following day frank hematuria was associated with severe lumbar and testicular pain and dysuria. The urine appeared grossly to be practically pure blood. Brisk bleeding occurred from the osteomyelitis fistula at the tip of the second left toe. A transfusion of 4 day old citrated blood was secured from the blood bank. No donors of the patient's type were immediately available. After the transfusion his hemoglobin was 76 per cent, red blood cells 4,000,000, white blood cells 8,200, polymorphonuclear leukocytes 76 per cent, lymphocytes 32 per cent, monocytes 2 per cent. On the fourteenth day the coagulation time rose to 15 minutes and the prothrombin time to 32 seconds, subsequently rising to 155 minutes and 54 seconds respectively in the ensuing ninety-six hours. On one occasion the patient vomited coffee ground vomitus. The temperature remained elevated. Despite the transfusion, vitamin K and vitamin C therapy and adequate sedation, hemorrhagic manifestations persisted. In addition to these manifestations the patient had a large sublingual ecchymosis and bladder retention.

A second transfusion, this time of freshly obtained blood, was given on the seventeenth day, after which the hemorrhagic manifestations began to subside, and the prothrombin and coagulation times dropped to normal over a seventy-two hour

period. On the nineteenth day a subconjunctival hemorrhage appeared and the hematuria had abated. The sublingual ecchymoses were resorbing. Microscopic hematuria persisted until the twentieth day, at which time the coagulation and prothrombin times attained normalcy. The total duration of the toxic manifestations was nine days.

In this case 1,700 mg of dicoumarin, administered orally in twelve divided doses, resulted in prolongation of coagulation and prothrombin times. The first effect of the drugs was noted after seven days. Toxic hemorrhagic manifestations of nine days' duration included lumbar and testicular pain, hematuria, purpura, hematemesis, spontaneous bleeding from the wound site, sublingual ecchymoses, subconjunctival hemorrhages, dysuria, bladder retention and temperature elevation. Transfusion of 4 day old citrated blood did not influence the course of these manifestations, while a transfusion of freshly secured blood resulted in subsidence within seventy-two hours. Massive doses of vitamins C and K had no effect.

CASE 6—A patient aged 60 weighing 127 pounds (57.6 Kg), with a diagnosis of diabetes mellitus, arteriosclerotic endarteritis obliterans and osteomyelitis of the right hallux, after a control period of seven days, had a prothrombin time of 20 seconds, a coagulation time of 7 to 9 minutes and a sedimentation rate of 72 mm an hour.

Dicoumarin was administered in 200 mg doses at twenty-four hour intervals over a period of twelve days. Three days after onset of therapy the prothrombin time rose to 27 seconds. The coagulation time showed no significant variation, however, until the seventh day after 1,400 mg of the drug had been administered, at which time a definite upswing was noted reaching 9 minutes 25 seconds. Administration of the drug was discontinued on the twelfth day (2,200 mg total). At this time the coagulation time was 13.5 minutes and the prothrombin time 28 seconds. Twenty-four hours later prolonged bleeding from minor lacerations sustained while shaving was noted. A capillary fragility test revealed 8 petechiae after fifteen minutes (normal). On the sixteenth day large ecchymoses involving both lumbar and inguinal regions were discovered on the right side. There was no associated lumbar costo-vertebral tenderness. The sedimentation rate rose from a previous reading of 75 to 132 mm an hour. A recheck of the capillary fragility revealed no significant deviation from normal. Venipuncture, despite great care, produced extensive ecchymoses at the needle site. Prothrombin and coagulation times had by this time attained 40 seconds and 16 minutes, respectively. Forty-eight hours later, on the eighteenth day, ecchymoses similar in character and distribution occurred on the contralateral left side. On the twenty-second day, ten days after the withdrawal of dicoumarin, both the coagulation and prothrombin curves began to descend, reaching normalcy on the twenty-ninth day. Ecchymoses showed progressive resorption, disappearing completely by the thirty-fourth day.

Administration of dicoumarin in doses of 200 mg every twenty-four hours produced an elevation of the prothrombin time after 600 mg had been administered and elevation of coagulation time after the administration of 1,400 mg. The capillary fragility revealed no significant deviation from normal. Venipuncture, despite great care, produced extensive ecchymoses at the needle site. Prothrombin or coagulation times attained 40 seconds and 16 minutes respectively. A total of 2,200 mg of the drug was given over a 12 day period. Twenty-four hours after the withdrawal of medication hemorrhagic manifestations appeared in the form of spontaneous bleeding from the wound in the right hallux. Other manifestations were huge ecchymoses in both lumbar and inguinal regions bilaterally.

The effect of the drug persisted for twenty-five days. Toxic manifestations were evident over a twenty-one day period.

It was noted throughout the series that a single large dose of 600 mg produced less physiologic and definitely less toxic effects than total equivalent doses administered in portions of 100 mg daily. This phenomenon was previously noted in animals by Link and his associates and attributed to imperfect intestinal absorption. The earliest toxic signs were most frequently noted to be lassitude and general malaise with aching in the costovertebral angles. Most interesting was the fact that in spite of the extensive hemorrhages in practically all parts of the body, and especially subcutaneously, in no instance was the capillary fragility found to be increased (method of Wright and Lihenfeld).¹⁶

At present we are using smaller doses and are able practically to eliminate this risk. It seems important to include these reports, however, since they may serve to familiarize future users of this substance with the

Chart 2 (case 6)—Response of coagulation and prothrombin times to administration of dicoumarin (total dose 2.2 Gm). The patient aged 60 weighing 127 pounds had diabetes mellitus and arteriosclerotic endarteritis.

possible complications so that they may be recognized early and treated properly. The prothrombin time (Fullerton modification of the Quick technique)¹⁷ was a rather good indication of the response of the patient to dicoumarin and the risk of hemorrhage. As can be seen from the figures in table 3, however, some patients had hemorrhages with prothrombin times which were much lower than those of others who never showed hemorrhagic manifestations. The use of a diluted plasma (25 per cent or 12.5 per cent) from animals as well as in man has resulted in greater sensitivity to variations in the prothrombin than undiluted plasma, thus reducing the risk of untoward reactions. The coagulation time (Lee-White two tube method)¹⁸ was not found to be as reliable a guide but should be followed.

16 Wright I S and Lihenfeld Alfred. Pharmacologic and Therapeutic Properties of Crystalline Vitamin C (Cevitamic Acid). Arch Int Med 57: 241 (Feb.) 1936.

18 Lee R I and White, P D. A Clinical Study of the Coagulation Time of the Blood. Am J M Sc 145: 195 (April) 1913.

We examined various factors in an endeavor to determine a possible cause for this variability. Analysis of the clinical and laboratory studies on our patients revealed

1 That the incidence of toxic reactions was not significantly influenced by age or sex.

2 That no significant correlation existed between malnutrition and frequency of toxic reactions. Nutritional status was estimated by weight-height tables, history and clinical impression and was good in all but 3 patients of whom none showed a hemorrhagic picture. There was no evidence of dehydration. The hematocrit studies, specific gravity of the plasma and serum proteins were within normal limits.

3 That no increase in capillary fragility (Wright-Lilienfeld method)¹⁶ was detected even in the hemorrhagic cases. Seven patients presented an increased capillary fragility before taking dicoumarin. Only 2 of these showed hemorrhagic manifestations, but these showed no further increase in capillary fragility.

4 That the incidence of either hypochlorhydria or achlorhydria was not significantly greater in the hemorrhagic group. Gastric analysis in the toxic group revealed normal hydrochloric acid concentration curves in 4, hyperchlorhydria in 1 and hypochlorhydria in 3. In the nontoxic group we found normal hydrochloric

synthetic vitamin K was administered parenterally, thereby eliminating the factor of variations in gastrointestinal absorption. Doses of 32 or 64 mg of synthetic vitamin K were given twice daily to 8 patients in whom the prothrombin time was prolonged above 36 seconds (Thirty-six seconds was arbitrarily selected, since it has been found that this represents an average potential or actual hemorrhagic level). In each instance half the daily dose of synthetic vitamin K was given by the intramuscular and half by the intravenous route. Eight patients with comparable prothrombin times were used as controls. Administration of dicoumarin was discontinued for several days prior to the institution of synthetic vitamin K therapy. To 4 patients vitamin K substitute was administered immediately after the appearance of hemorrhage. In a fifth patient hemorrhagic manifestations developed eighteen hours after synthetic vitamin K therapy had been begun. The remaining 3 patients showed no bleeding tendency. Three patients in the control group showed bleeding while 5 were free from hemorrhage. Table 4 illustrates the effect of synthetic vitamin K on the hypoprothrombinemia produced by administration of dicoumarin. The dose of dicoumarin, duration of dicoumarin therapy and the dose of vitamin K substitute together with prothrombin times obtained during the course of vita-

TABLE 4—Effect of Vitamin K Substitute on Dicoumarin Induced Hypoprothrombinemia

acid curves in 6, hypochlorhydria in 3 and hyperchlorhydria in 2 cases.

5 That toxicity on the basis of retention due to renal dysfunction could not be established in our cases presenting hemorrhages although urea nitrogen, non-protein nitrogen, urea clearance and urinary studies were carried out with this in mind.

6 That most of these patients were treated during the hot summer months and that Link¹⁹ has observed that an abnormally high environmental temperature may enhance the action of dicoumarin in animals. We cannot make a definite conclusion regarding this factor at present.

7 The question as to whether liver damage acts as the mechanism by which the prothrombin is inactivated is still not definitely decided. Icteric index, bromsulphalein, cholesterol-ester ratio, Takata-Ara and total protein studies have been carried out on certain of our patients without demonstrating any conclusive liver damage as a result of the administration of dicoumarin. It was thought that more complete studies with large doses of vitamin K might throw further light on the fundamental mechanism involved in the action of this substance. Accordingly a potent synthetic vitamin K²⁰ was used to determine its effect on the hypoprothrombinemia and on the hemorrhagic manifestations produced by the oral administration of dicoumarin.²¹ The

min K therapy are indicated. Similar data on 1 patient who received no synthetic vitamin K are included for comparison. In an interpretation of these curves it is important to bear in mind that withdrawal of dicoumarin of itself will be followed by a return of prothrombin time to normal over a period which varies with the dose of dicoumarin, duration of therapy and susceptibility of the patient. It should be emphasized that Andrus, Kark and Sauter,²² using similar doses of vitamin K substitute, were able to restore prothrombin concentrations to normal within twenty-four to forty-eight hours in a series of patients with hypoprothrombinemia due to causes other than dicoumarin administration. Patients who failed to respond in twenty-four to forty-eight hours were termed vitamin K refractory. In the light of observations made by the aforementioned authors, the alteration in prothrombin time cannot be attributed to synthetic vitamin K in our patients. The time required for restoration of normal prothrombin levels in patients who received vitamin K substitute did not vary significantly from those noted in controls. Chart 5 graphically illustrates the absence of effect of the vitamin K substitute on the prolongation of prothrombin time in a typical case of dicoumarin induced hypoprothrombinemia.

Table 5 illustrates the effect of administration of the vitamin K substitute on hemorrhages complicating the hypoprothrombinemia produced by dicoumarin. Spontaneous bleeding associated with hypoprothrombinemia due to causes other than dicoumarin administration

can be controlled by comparable doses of vitamin K substitute in from eight to twenty-four hours provided hepatic damage is not present. The data in this table show that despite adequate synthetic vitamin K therapy hemorrhages persisted for from four to nine days. In some instances hemorrhages required transfusion for control. No significant variations in the intensity or duration of hemorrhagic complications were observed between the patients who received vitamin K substitute and those who did not.

Chart 6 demonstrates the absence of a prophylactic effect of administration of synthetic vitamin K on the hemorrhagic tendency, which occasionally occurs with dicoumarin induced hypoprothrombinemia. This patient received 128 mg of vitamin K substitute for forty-eight hours prior to the development of hemorrhage despite which he bled profusely. Because of the severity of the hemorrhage, a transfusion with 6 day old bank blood was given on the sixth day. Hemorrhage was finally controlled on the ninth day, as previously mentioned. It was later found that bank blood more than 72 hours old is ineffectual in the treatment of this condition. The foregoing data indicate that the hypoprothrombinemia and bleeding induced by the administration of dicoumarin is refractory to this therapy with synthetic vitamin K given in doses which are greater than those which control hypoprothrombinemia from other causes. The evidence does not warrant the conclusion, however, that this failure in response to synthetic vitamin K is on the basis of hepatic damage similar to that produced by chlorotom and phosphorus. Hypoprothrombinemia of the degree by dicoumarin administration in this series, if due to liver damage, would represent decided destruction of hepatic parenchyma. Destruction of this magnitude is probably incompatible with recovery over the brief period required for restoration of prothrombin time to normal following dicoumarin withdrawal, and especially the rapid restoration following fresh blood transfusions.

Bingham, Meyer and Pohle¹⁴ presented further evidence against the action of dicoumarin being based on severe liver damage. Even when their dogs were given fatal doses there were no gross or microscopic lesions which could be attributed to the substance administered. They hypothesized the possibilities that the formation of prothrombin in the liver is physiologically inhibited and the latent period (twenty-four hours or more) before a detectable change is noticed in the prothrombin time may represent a period necessary for the using up of the prothrombin available in the blood. Other reservoirs about which little is known may also be drained during this period. Additional possibilities may be suggested but thus far are not proved. The latent phase may be due to the need for dicoumarin to undergo certain changes before it is capable of acting, or a protective mechanism may be promptly set up which temporarily inhibits the action of dicoumarin against prothrombin but later fails to continue this protection. The prothrombin produced or liberated into the blood stream may later be inactivated by dicoumarin which it appears may also inactivate both the vitamin K present in the body and any additional synthetic vitamin K taken while the dicoumarin is present. The knowledge regarding the mechanism by which dicoumarin acts is thus seen to be relatively limited, although new and interesting conditions are constantly being discovered.

THE THERAPEUTIC VALUE

The therapeutic value of this dicoumarin has not yet been clearly established. Because of its obvious theoretical value as a valuable adjunct in an anticoagulant therapy, several groups of workers have attempted the difficult task of evaluating it. Our own efforts during the first year of study of its use in man have been concentrated on studying the mechanism, the untoward effects, the treatment of these untoward effects and the determination of a safe but pharmacologically active dosage. We have administered this drug to 40 patients who have been carefully followed as to prothrombin time, coagulation time, bleeding time, capillary fragility, evidences of hemorrhage, tests for kidney and liver function and blood counts. Additional studies have been carried out in some. We cannot draw conclusions from this small group but will present certain facts and experiences which may be of value to others undertaking to use this substance. Unfortunate complications may thus be minimized.

One of the most interesting groups of patients for study with this anticoagulant falls in the general category of thrombophlebitis. We have used it on

Chart 6 (case 5).—Response of prothrombin time to 36.4 mg of dicoumarin per kilogram in eighteen days. H indicates hemorrhage, C cessation of hemorrhage, T transfusion, B bank blood, F fresh blood.

10 such patients who have been carefully followed. In our studies dicoumarin was administered only by mouth. In order to determine the size and frequency of the dose of dicoumarin necessary to obtain the desired effects and still avoid untoward complications, it is advisable to carry out daily prothrombin and coagulation determinations. As previously stated, wide variations in susceptibility to dicoumarin have been observed in different patients. Unfortunately we have as yet been unable to identify the cause of this phenomenon. The time required for the initial effect to manifest itself is a poor guide in estimating susceptibility unless prothrombin time estimations are performed on diluted plasma. Twenty-five per cent diluted plasma renders possible the detection of slight fluctuations in prothrombin concentration which escape observation if undiluted plasma is used. In order to secure an unequivocal end point, dilutions should be made with a saline solution of fibrinogen 600 mg per hundred cubic centimeters. The variations in diluted plasma prothrombin time and the duration of the latent period serve as a fairly satisfactory but not infallible guide to planning a dosage schedule. On the basis of observations that single doses give rise to alterations in the prothrombin time which can be represented by parabolic curves, we have attempted to maintain fairly constant prolongation of prothrombin time by administering an effective dose and

varying the interval, so that a succession of peak effects is obtained. We thus attempted to maintain the prothrombin time at the level desired with minor fluctuations. While this is usually possible, the prothrombin time frequently becomes so prolonged that a longer period between doses becomes necessary.

The majority of the patients in this series received 300 mg after breakfast daily the first two or three days. Subsequent doses were administered at two to three day intervals, depending on the degree of prothrombin time prolongation obtained with 25 per cent diluted plasma. The levels between which we have attempted to maintain prothrombin times are 30 to 35 seconds for undiluted plasma and 70 to 90 seconds for 25 per cent diluted plasma. Hence when prothrombin time falls below 30/70 a dose is indicated. If, however, the prothrombin time exceeds 35/90, dicoumarin is withheld.

Occasionally the prothrombin time may fall rapidly and attain normal levels before the effect of subsequent doses is noted. In such instances we have experimentally attempted to enhance dicoumarin absorption by simultaneous administration of sodium bicarbonate in 1 Gm doses. This was done on the basis of the knowledge that, as the dicoumarin is soluble only in an alkaline medium, absorption and hence the pharmacologic characteristic effects might be hastened. This procedure has met with little or no success. The usual latent period seems to be inevitable, as pointed out by Bingham, Meyer and Pohle on the basis of their intravenous studies. We have not used doses calculated on the basis of milligrams per kilogram of body weight since the factor of intestinal absorption has been shown to be variable. It is also much simpler to utilize a standard capsule. As many as needed may be administered. Of the ten patients 8 showed prompt and uncomplicated recovery, with subsidence of clinical evidence of activity of the process within three to ten days.

Two patients, both suffering from recurrent migratory thrombophlebitis, suffered relapses when the prothrombin time returned to normal levels after dicoumarin therapy. In 1 instance (E S) relapse consisted of a brief episode of redness and tenderness of a previously involved left saphenous vein with tachycardia and increased sedimentation rate, when in the course of the therapy the prothrombin time was permitted to drop to 25 seconds (54 seconds with dilution to 25 per cent). Increased dosage with further prolongation of the prothrombin time was accompanied by recovery with no further complications. Results in the other patient (J T), also suffering from recurrent migratory thrombophlebitis, must be considered as unsuccessful from the point of view of dicoumarin therapy.

J T, admitted to the New York Post-Graduate Hospital on Sept. 20, 1941, had phlebitis involving several areas of the saphenous veins of both legs. With rest in bed and small doses of sulfadiazine the activity had subsided by October 10. Dicoumarin was administered in 300 mg doses on the first, second, third, fourth, seventh, eighth, twelfth and thirteenth days, a total of 2.4 Gm (459 milligrams per kilogram), maintaining the prothrombin time between 26 and 46 seconds and the coagulation time between 7 and 12 minutes. By October 30 the phlebitis had apparently subsided and by November 8 the sedimentation rate, which during activity had reached 41, had subsided to a normal level of 9 (Westgren method). On December 10 he had a recurrence and on December 12 dicoumarin was started. This time he received the following dosage:

300 mg on the first, second, fourth, sixth, tenth, twelfth, sixteenth, nineteenth, twenty-second and twenty-sixth days, a total of 3 Gm (576 milligrams per kilogram). By December 17 his phlebitis had subsided but on December 22, while his prothrombin time was 37 seconds, two new areas of thrombophlebitis developed. (This is the only time we have seen this occur with a considerably prolonged prothrombin time due to dicoumarin.) The dicoumarin was continued and the phlebitis had subsided by Jan. 3, 1942, at which time the drug was discontinued. On February 9 another episode of active thrombophlebitis occurred and dicoumarin was started February 11. This time he received 300 mg of dicoumarin on the first, second, fourth, seventh, eighth, ninth, eleventh, fourteenth, sixteenth, twenty-first, twenty-second and twenty-third days, a total of 3.6 Gm (692 milligrams per kilogram). Improvement followed the administration of the substance and the patient was allowed out of bed on March 3. On March 10, when the prothrombin time was 26 seconds (60 seconds with 25 per cent diluted plasma), an acute depressive state developed and the patient had to be transferred to the Bellevue psychiatric wards.

We must conclude, therefore, that in spite of large doses of dicoumarin we could not prevent the recurrence and progression of the migratory thrombophlebitis in this instance.

The other patients, including 2 with recurring migratory thrombophlebitis, were apparently helped by dicoumarin, although we cannot draw any further conclusions regarding its therapeutic value in so small a series of such an unpredictable disease. This series will be enlarged during the next year. It has seemed wise to present the histories given briefly in order that new workers may appreciate some of the problems involved.

We shall now summarize briefly some of the interesting results of the laboratory studies which have been carried out on these and other patients. In 15 cases in which hematocrit readings were followed they were found to be within the normal range before and during the administration of dicoumarin. In 15 cases in which the bleeding time (Ivy method) was followed a considerable variation in response to dicoumarin was noted. All but 1 patient showed some prolongation, but this varied from a very slight prolongation as from 2 minutes 30 seconds to 3 minutes 15 seconds to a definite prolongation as from 2 minutes 30 seconds to 10 minutes 35 seconds. The extent of the increase in bleeding time bore no direct relationship to the extent of increase in the prothrombin time in different patients, although the general trend was parallel. In a single case the peak in prothrombin time frequently but not always coincided with the peak in bleeding time. Clot retraction studies have been carried out in 12 cases with the McFarlane technic. The normal standard is 38 to 50 per cent. The changes encountered as a result of administering dicoumarin may best be presented by listing the ranges encountered: C L, 48 to 21 per cent, E S, 44 to 32.1 per cent, I P, 43.8 to 21 per cent, S M, 44 to 30 per cent, D S, 46 to 33 per cent, S F, 34 to 28 per cent, A L, 42 to 38 per cent, M G, 56 to 26 per cent, H B, 46 to 38 per cent, J T, 59 to 21 per cent, D L, 42 to 28 per cent, F T, 44 to 21 per cent. In most instances maximum clot retraction changes coincided with maximum prothrombin time changes but in the case of E S and of F T this was not so. The following liver function tests have been performed on all of our patients before and during dicoumarin therapy: bromsulphalein, icteric index, cholesterol-ester ratio and plasma proteins. In addition,

when further data were desired the Takata-Ara test was performed. In our entire series of 40 patients we have failed to find any evidence of liver damage as indicated by these tests. This, as pointed out, is of especial interest and significance in the use of dicoumarin. The renal function has been checked before and during dicoumarin therapy with the urea clearance and the Mosenthal two hour urinary function test. In several instances the urea nitrogen-nonprotein nitrogen ratio was determined. All but 3 patients showed normal renal concentrating capacity on the basis of the two hour Mosenthal test. Other tests of the renal function on these patients failed to reveal any evidence of renal damage. Platelet counts were followed during treatment of 15 patients with no deviation from the normal range in any instance. As previously mentioned, one of the most interesting findings was the total lack of consistent change in the capillary fragility as determined by the positive pressure method (Wright and Lilenfeld). Even in the cases in which extensive ecchymosis and bleeding develops slight variations occurred which were unrelated to prothrombin or coagulation times or any other findings. Observations were made in all 40 cases. This is directly contrary to the findings in frank scurvy, in which bleeding and ecchymosis are almost invariably accompanied by increased capillary fragility as determined by this method.

The influence of the dicoumarin on the suspension stability of the blood as manifested by the sedimentation rate was of interest. In our experience the administration of dicoumarin per se was not accompanied by an increased sedimentation rate (Westergren method). Variations consistent with the pathologic state occurred in patients suffering from phlebitis, infection or a hemorrhagic state produced by dicoumarin. In other words, prolongation of the prothrombin time and clotting time due to dicoumarin administration unaccompanied by any of the aforementioned complicating factors was not accompanied by an increased sedimentation rate. In addition to the patients with thrombophlebitis the remaining patients in our series were suffering from arteriosclerosis obliterans or thromboangitis obliterans. Again we were dealing with diseases which are chronic and in many instances unpredictable as to course. We have quite consistently noted an increased tendency to bleed at the site of ulceration or gangrene. This may be explained by the findings of Bingham, Meyer and Pohle¹⁴ of the significant dilatation of the minute vessels of dogs who received dicoumarin whether they died from this substance or were killed for the study. We cannot, however, at this time arrive at any definite conclusions as to whether this increased bleeding is actually accompanied by an accelerated rate of healing. We have as yet seen no additional evidence of therapeutic value of dicoumarin in these diseases.

COMMENT

An attempt has been made to present briefly the historical and experimental background which led to the use of dicoumarin in man. Problems regarding the mechanism of the action of dicoumarin have been discussed. The results of studies of the effect of this substance on the prothrombin time, coagulation time, bleeding time, clot retraction, sedimentation rate, liver function, renal function, capillary fragility, blood count, response to therapy with vitamins C, P and K and other factors have been presented.

The complications which may be encountered in the use of dicoumarin and the treatment of these complications have been described. The therapeutic discussion has been limited to a consideration of dosage and to the effect of this substance on patients suffering with thrombophlebitis, thromboangitis obliterans and arteriosclerosis obliterans. The first year and a half of this study was for the most part devoted to the mechanism and pharmacologic action of dicoumarin in man. It is expected that therapeutic considerations will occupy a more prominent part in future studies.

THE EFFECTS OF EXPERIMENTAL ADMINISTRATION OF DICOUMARIN

3,3'-METHYLENE BIS-(4-HYDROXYCOUMARIN)

JESSE L. BOLLMAN, M.D.

AND

FREDERICK W. PRESTON, M.D.

ROCHESTER, MINN.

The identification and synthesis of the hemorrhagic agent of hemorrhagic sweet clover disease, dicoumarin [3,3'-methylene-bis-(4-hydroxycoumarin)], by Link and his associates¹ have provided a pure substance which can be administered to animals and man and cause a considerable diminution of the prothrombin content of the blood. Their paper carried also the obvious suggestion that this compound might be of value in clinical conditions when interference with the coagulability and prothrombin content of blood was desirable. Since the most probable use of this substance in clinical medicine is in the prevention of thrombosis, its value in such conditions can be determined only by clinical trial. However, several questions should be answered by experiments with animals. First, does the lowering of the prothrombin content of the blood by this drug prevent or delay experimental thrombosis? Second, can the drug be given in amounts sufficient to produce the desired effects without producing untoward reactions? Third, can the effects of the drug be controlled? Fourth, what factors alter the effectiveness of this drug? Satisfactory answers to some of these questions have been given in reports by Link and his associates,² by Butt, Allen and Bollman³ and by Bingham, Meyer and Pohle.⁴

In this report we wish to add further data which indicate that certain experimental forms of thrombosis may be prevented or delayed by the administration of dicoumarin. Additional studies substantiate the follow-

ing statements. The effect of the drug in reducing the prothrombin of the blood is uniform in dogs, and the amount of change is, within limits, proportional to the amount administered. Similar effects are produced when administration of the drug is repeated. Excessive amounts do not produce gross or microscopic evidence of injury to any specific tissue, and the animals appear normal when the administration of the drug has been discontinued. Excessive bleeding does not occur when operation is performed on dicoumarinized animals except in those which have been given excessive amounts for prolonged periods. The prothrombin time of the blood of dicoumarinized dogs and the bleeding tendency may be reduced by transfusions of fresh whole blood. Dogs receiving large amounts of sulfathiazole react in normal manner to dicoumarin. We should emphasize that inanition or experimental hepatic or renal damage produced in dogs greatly increases the effectiveness of dicoumarin and that due caution should be exercised in administering this drug to patients in the presence of any of these defects.

Chart 1—The effect of oral administration of dicoumarin on the coagulation time and prothrombin time (dog). At the time of the first transfusion the dog had been bleeding from a slight abrasion for three days and was extremely anemic. The bleeding stopped a few minutes after transfusion. At the time of the second transfusion slow bleeding from a venipuncture wound had continued for two days. Bleeding ceased a few minutes after transfusion.

EXPERIMENTAL PROCEDURE

It was found that a definite decrease of the prothrombin content of the blood of dogs could be maintained after forty-eight hours by daily administration of dicoumarin in amounts equivalent to 1 mg for each kilogram of body weight, the material being equally effective as the dry powder by mouth or injected intravenously as an alkaline solution. By daily administration of small amounts of this drug the prothrombin time of the blood could be maintained at approximately two or three times the normal value of 10 seconds (dogs) for at least six weeks, with no other apparent change in the condition of the animal.

The prothrombin content of the blood was determined by a slight modification of Quick's method. Nine volumes of blood were added immediately to one volume of 1.34 per cent solution of sodium oxalate. After

centrifugation 0.1 cc of this plasma was added to 0.1 cc of Quick's acetone washed rabbit brain thromboplastin and the mixture placed in a water bath at 37 C for five minutes. The prothrombin time was taken as the time required for coagulation after addition of 0.1 cc of 1.11 per cent solution of calcium chloride. With normal canine blood the prothrombin time was usually 9 to 10 seconds, the duplicate determinations checking within 1 second. When longer times are required, a wider variation is found in duplicate determinations, but since with undiluted plasma such times represent only a small percentage of the normal amount of prothrombin, such differences are insignificant in these experiments. Prothrombin times of less than 30 seconds were checked further by dilution of the plasma to 50, 25 and 12.5 per cent of its concentration with saline solution.

The coagulation time was determined at room temperature after blood had been taken by venipuncture in a saline washed syringe. The blood was placed immediately in a small tube which was inverted every thirty seconds after five minutes and every minute after ten minutes. In these studies no appreciable change of coagulation time was found unless the prothrombin time of the blood was prolonged more than five seconds beyond the normal value. When extremely small amounts of prothrombin were present coagulation time was usually much delayed, roughly in proportion to the loss of prothrombin.

No definite gross or microscopic pathologic change of any organs was found after administration of large amounts of dicoumarin. Twenty-four to forty-eight hours after the oral or intravenous administration of 100 mg for each kilogram of body weight there was widespread dilatation of the small blood vessels of the liver with noticeable filling of all blood sinusoids of the liver. The hepatic cells did not appear abnormal but some of the stellate cells had engulfed some lipid staining material. The results of dye retention tests for liver function had been within normal limits, and there was no retention of bile pigment. Necropsy was performed also on other dogs which had received 10 to 20 mg daily for six weeks and to which repeated transfusions had been given to prevent fatal hemorrhage. Such animals usually showed petechial hemorrhagic regions in all organs, especially in the liver, kidneys and spleen, but there were no changes that could not be attributed entirely to the hemorrhage. These changes had disappeared entirely in other dogs similarly treated but allowed to recover for two weeks after discontinuation of the drug.

Our observations are in conformity with those of Link that the hemorrhagic condition characteristic of the sweet clover disease does not appear unless dicoumarin is fed or injected continuously over a period of time. The development of the hemorrhagic condition is more than a function of time since animals may be maintained for several weeks with a prothrombin time two to three times elevated by intermittent administration of the drug and without any untoward effects being apparent. With larger amounts of the drug daily administered the prothrombin time is elevated further and the hemorrhagic condition appears in from ten to twenty days with no further change of the coagulation time or the prothrombin time. Apparently some additional factor is necessary for the development of the hemor-

rhagic condition. The imminent development of the hemorrhagic condition in dogs usually is detected by the appearance of continuous bleeding from a venipuncture wound two or three days prior to death from the hemorrhagic condition. Transfusion of fresh whole blood at this time stops the bleeding from venipuncture wounds in a few minutes (chart 1). The coagulation time and prothrombin time of the blood return toward normal. Extensive surgical procedures have been carried out in dicoumarinized dogs that had greatly altered prothrombin content of the blood at various times before the development of the hemorrhagic condition. The bleeding occasioned by the surgical procedures has been surprisingly small, not materially greater than that which would obtain in normal dogs, and in great contrast to the bleeding which occurs in dogs that have prolonged coagulation time due to heparin.

The response of individual dogs to a single intravenous injection of 10 mg of dicoumarin for each kilogram of body weight was found to be fairly uniform. The plasma prothrombin fell to about 15 per cent of normal within three days and returned to normal within eight days. An increase of prothrombin time was apparent within twenty-four hours and the prothrombin time increased by the third day to about 90 seconds (normal 10 seconds). Some decline was apparent on the fourth day and almost normal values were observed by the sixth day. There was little alteration of the coagulation time of the blood during this period. The results of tests for heparin in the blood, by neutralization with protamine, were entirely negative. The intravenous injection of heparin at any time did not alter the prothrombin content of the blood although it definitely delayed coagulation time during its period of activity. The rate of disappearance of injected heparin from the blood and its effectiveness in delaying coagulation were not materially different in dicoumarinized dogs and in normal animals. Apparently the rapid elimination of heparin from the blood was the limiting factor in these experiments.

Renal damage was produced in 4 dogs by the subcutaneous injection of uranium acetate (20 to 30 mg for each kilogram of body weight in divided doses) at various times after they had received 10 mg of the dicoumarin compound for each kilogram of body weight. In these dogs the prothrombin of the blood was subsequently reduced to less than 6 per cent of normal and the prothrombin time increased beyond 120 seconds. The prothrombin content of the blood remained depressed for eight, thirteen, fourteen and fifteen days respectively. Total anuria was produced in 2 additional dogs, in 1 by bilateral nephrectomy and in the other by bilateral ligation of the ureters, two days after they had received a similar amount of the drug. In both cases the prothrombin fell to less than 5 per cent of the normal value within forty-eight hours and the prothrombin times were 150 and 195 seconds. Both dogs died on the third postoperative day with extensive hemorrhage into their peritoneal cavities. We were unsuccessful in our attempts to produce anuria in dogs during the period of dicoumarinization by oral administration of large amounts of sulfathiazole and the changes of the blood prothrombin were similar to those expected from the dicoumarin. The greatly increased activity of dicoumarin during periods of renal damage is striking (chart 2). In view of the facts reported by Link and his associates that they were unable to detect dicoumarin in the urine of dogs after administration

of large amounts, it may be suggested that the kidney plays an important role in the destruction of this compound.

A mild degree of hepatic damage was produced in dogs which were exposed to carbon tetrachloride vapor for thirty minutes each day. This amount of exposure produced slight bilirubinemia but did not lower the prothrombin content of the blood. Administration of the dicoumarin compound 10 mg for each kilogram of body weight, reduced the prothrombin content of the blood more and for periods of days three to five times longer than similar amounts of dicoumarin before exposure of the same animal to carbon tetrachloride.

Animals fasting for seven days or longer were likewise more susceptible to the effects of dicoumarin. Animals that received vitamin K_1 , 2 to 5 mg daily during fasting usually responded like normal animals when dicoumarin was given. When vitamin K_1 was given to fasting dogs two or three days after dicoumarin had been given, the effect was less pronounced than the

Chart 2—The effects of renal injury after administration of dicoumarin on the prothrombin time of the blood. The first curve is typical for the response of a normal dog and the second curve shows the exaggerated response due to renal injury. This response was much greater in animals after bilateral nephrectomy or ligation of both ureters.

effects of food. Animals fed two or three days after fasting and administration of dicoumarin showed a return of their plasma prothrombin to normal within twenty-four hours.

Murry and Janes⁶ found that heparin must be injected in amounts sufficient to keep the coagulation time of the blood greater than 13 minutes in order to prevent thrombosis of glass cannulas placed in the carotid arteries of dogs. When heparin was not given to control dogs the cannulas thrombosed in about twenty minutes, but they remained patent for more than twenty-four hours in the heparinized dogs. We performed similar experiments by placing glass cannulas in the carotid and femoral arteries of normal and dicoumarinized dogs. In the dicoumarinized dogs in which the prothrombin time was elevated beyond 30 seconds the cannulas remained patent for six to eight

6 Murry, Gordon and Jane, J. M. Prevention of Acute Failure of Circulation Following Injury to Large Arteries. Experiments with Glass Cannulas Kept Patent by Administration of Heparin. *Brit. M. J.* 2: 67 (July 6) 1940.

hours, when the experiments were terminated. Our control series was similar to that of Murry and Janes except that an occasional cannula would remain patent for several hours.

Other experiments were performed in which blood was clamped in portions of the jugular and femoral veins with soft clamps. This blood did not clot in normal dogs for several hours, but it was found that fresh blood injected by syringe into the occluded vein clotted within a few minutes. When this clot was allowed to be washed out by removal of the clamps and the blood was allowed to flow through the veins for fifteen minutes, subsequent blood held in the same veins by clamps clotted within ten minutes. The clot could be washed out again and the process repeated many times. Similar procedures in dicoumarinized dogs with prothrombin times greater than 30 seconds showed definite evidence of delayed thrombosis in the occluded veins. Normal blood injected into the occluded veins coagulated in a few minutes, but when this clot was washed out for a few minutes subsequent occlusion of the veins did not cause the animal's own blood to clot at any time in less than thirty minutes and usually no clot was found after several hours. When coagulation did occur in the veins of the dicoumarinized animals the clot was softer and more friable than in the normal animals. After the dicoumarin clot had been washed out of the vein, coagulation was no more rapid in subsequent occlusions.

We have used dicoumarin to replace heparin in many experiments in the physiologic laboratory. Cannulas of glass or metal which rapidly thrombose in the blood vessels of normal dogs have been maintained patent in dicoumarinized dogs during the course of experiments lasting six to eight hours. The procedure that we have found satisfactory is to give orally 10 mg. of the drug for each kilogram of body weight on the first day and 5 mg. per kilogram on each subsequent day. After the third day the prothrombin time of the blood is 30 to 45 seconds or more, and we have always used such animals for the experiments before the seventh day.

SUMMARY

Studies which have shown that dicoumarin prolongs the prothrombin and the coagulation time in animals have been confirmed by studies on dogs. No harmful effects during or after the administration of this compound were found in dogs which were maintained for six weeks with prothrombin times two to three times normal. Continuous administration of excessive amounts of this compound produces in dogs a condition similar to that found in the hemorrhagic sweet clover disease. The prothrombin time of the blood and the bleeding tendency may be partly controlled by transfusion of fresh whole blood. Vitamin K deficiency, inanition or hepatic or renal injury greatly exaggerates the effect of this drug. The administration of large amounts of sulfathiazole does not alter the effectiveness of the dicoumarin compound. The action of heparin is not prolonged when given to dicoumarinized animals and heparin is not involved in the action of dicoumarin.

The tendency toward thrombosis, as demonstrated experimentally by the thrombosis of glass or metal cannulas interposed in arteries or by thrombosis in occluded veins is greatly reduced in animals that have prolonged prothrombin times due to the administration of this drug.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. ALLEN, BARKER AND WAUGH,
DRS. WRIGHT AND PRANDONI AND DRS.
BOLLMAN AND PRESTON

DR. SHEPARD SHAPIRO, New York. This *in vivo* anticoagulant dicumarol is to the investigator and the clinician a new instrument. It might aid in the further elucidation of the mechanism of blood clotting, it might help in the further determination of the chemical nature of prothrombin. It may be utilized in operative procedures in which it is required that the blood be maintained in a noncoagulable state. The evidence presented here today, and that presented by other workers, has shown that dicumarol may be used therapeutically when anticoagulant effects are desired. Because of the latent period between administration and detectable response, it is not applicable when immediate action is sought. It should be realized that the administration of an anticoagulant involves an element of risk by reason of the interference with a fundamental property of the blood, namely, clotting. Dicumarol is an *in vivo* anticoagulant by virtue of its selective toxic action, whereby it interferes with the elaboration of prothrombin. Its use as a therapeutic agent already implies the presence in the patient of a disturbed state as a result of the existing disease. Hence the tolerance observed in normal persons may prove to be an unreliable guide in such cases. It is therefore necessary, as emphasized by Dr. Allen and his co-workers, to individualize the dosage level by frequent estimations of the prothrombin times. Drs. Sherwin, Redish, Campbell and myself have found it necessary to increase the sensitivity of the prothrombin estimations. Using the technique as described by Prof. Karl Paul Link and his students, the prothrombin times of whole and diluted plasma are estimated at the same time. We strongly recommend the prothrombin estimation of 125 per cent, as well as whole plasma, as a guide to dosage. We have found that it is safe for therapeutic purposes to give a quantity of dicumarol which will result in a prolongation of the prothrombin time of the diluted (125 per cent) plasma to between twice and three times the normal figure while that of the whole plasma is maintained at less than double the normal value. By observing this rule it has been possible to give dicumarol intermittently for months without difficulty. It is interesting that, when fed during the menstrual period, this substance has not significantly altered this function.

DR. K. K. CHEN, Indianapolis. These contributions constitute the beginning of the last chapter of this subject, completing the logical sequence of introduction of any new drug if the therapeutic values can be finally established. Through the arrangement of the Wisconsin Alumni Research Foundation, the product has been placed in several medical centers for experimental investigation. As Dr. Shapiro announced, the word dicumarol has been adopted by the foundation, and, no doubt, will be submitted to the government and the Council on Pharmacy and Chemistry for final approval. Much of the toxicologic work has been presented by Dr. Meyer of Wisconsin. Many additions have been made by Dr. Bollman. During the last year it has been my privilege to study the effects of dicumarol in a large number of animals. Dicumarol may cause two types of deaths: the acute and the subacute. If a single dose of dicumarol of from 60 to 80 mg. per kilogram is injected intravenously, or one of 500 to 700 mg. per kilogram is given by mouth, the animals gradually develop elevation of rectal temperature and clonic convulsions and die within a few hours from circulatory collapse. The prothrombin time in those animals is not altered, and naturally no bleeding can be demonstrated at postmortem examination. If dicumarol is repeatedly administered, a different picture results. In rabbits an intravenous injection of 1 mg. per kilogram daily will invariably cause death, and in dogs daily doses of 5 mg. per kilogram uniformly produce death. In mice and rats the feeding of 0.01 per cent of dicumarol in food is uniformly fatal. Please note that these are small doses, given repeatedly. Those animals, of course, have very great prolongation of their prothrombin time, and death usually occurs within ten to thirty days. At postmortem they will show hemorrhages in various tissues and organs. Pulmonary edema is frequently encountered.

and secondary anemia is certainly obvious. In rats we have observed in almost 50 per cent of the cases central necrosis of the liver, and we have also observed occasionally central necrosis of the liver in mice, rabbits and rats. These data clearly indicate that dicoumarol is a drug of high potency and also of high toxicity. My experiments were conducted under the most severe conditions and these results should not be used as arguments against careful clinical trials. It is possible that if these doses were reduced they would be perfectly harmless to these animals. Nevertheless the drug must be given by certain criteria, such as the determination of the prothrombin time or other appropriate tests. Otherwise unfortunate accidents may arise.

CLINICAL EXPERIENCES WITH DICOUMARIN

3,3'-METHYLENE BIS-(4-HYDROXYCOUMARIN)

WINFIELD L. BUISCH, M.D.

AND

JOHN D. STEWART, M.D.

BUFFALO

The dicoumarin compound [3,3'-methylene-bis-(4-hydroxycoumarin)] is a white, crystalline, insoluble powder. The brilliant work of Campbell and Link¹ resulted in its preparation and identification as the hemorrhagic agent causing the death of cattle eating spoiled sweet clover. Butt, Allen and Bollman² first reported its clinical use in prolonging the prothrombin and clotting times of the blood. The response of 150 patients to the administration of this drug forms the subject of this report.

DOSE

The dose employed varied in size from 300 mg the first day followed by 200 mg the second day up to a 300 mg dose for three successive days, given orally. In chart 1 is represented graphically the effect of the smallest dose used contrasted with the largest dose used. The prothrombin time was determined by the method of Quick.³ The clotting time of the blood is elevated similarly to the prothrombin time. The larger dose produced a prothrombin time of more than 180 seconds at one time or another in half of the patients to whom it was given. However, the clotting time by the method of Lee and White⁴ rarely rose above 25 minutes. Certainly this larger dose produces a sufficient response as to both extent and duration. The smaller dose did not cause a sufficiently consistent effect.

In chart 2 is represented graphically two doses of intermediate size. These did not produce the decided increase of the prothrombin time except on a rare occasion. The dose of 300 mg on two successive days was sufficient to prolong the prothrombin time

and coagulation time in nearly every instance. We believe that it should be used as the basic dose for routine use. In the occasional case blood determinations may show that an additional 300 mg is advisable. Twenty-four to forty-eight hours are required for the effect to become apparent in the blood following oral administration. Usually it is forty-eight hours.

Two hundred mg on two successive days proved to be a satisfactory dose for children. Unpleasant or deleterious side effects were not noted, with the exception of bleeding phenomena to be noted later.

INDICATIONS

We have been especially interested in the use of this drug as a prophylactic measure against postoperative thromboses and embolism. With a few exceptions the patients comprising this series have had the drug administered the day after an operation. Some have even had it given two days before an operation. In the 130 patients who received this drug and were operated on wound healing took place in the normal manner, with 3 exceptions—small hematomas developed in 2 and the third had a large hematoma that required operative evacuation of the clot and ligation of a bleeding vessel.

Chart 1—Effect of dicoumarin on prothrombin time (normal equals 16 seconds). Curve marked off by black circles produced with 300 mg dose given orally daily for first three days. Curve marked off by white circles produced with smaller dose (200 mg for first two days).

Two patients with clinical pulmonary embolism and hemoptysis were later given dicoumarin. The hemoptysis was not aggravated and further embolic phenomena did not occur.

Six patients with thrombophlebitis of the long saphenous or femoral veins were treated with dicoumarin compound. In five days the tenderness had disappeared and the swelling had subsided. The patients were then urged to walk about with elastic bandages on the affected extremity. Two patients had a recurrence of the thrombophlebitis, one in the same leg and the other in the arm. The recurrence took place two weeks after the drug was administered, which coincides with the time that the drug effect disappears. At the present time we are administering the drug in at least weekly intervals in order to maintain its effect for at least four weeks.

We have not had occasion to use this drug in combination with the sulfonamides in certain infections but believe that it is deserving of trial.

The use of dicoumarin compound in 2 cases of threatened gangrene of the leg due to arteriosclerosis obliterans did not prevent the occurrence of the gangrene.

The clinical course of rheumatoid arthritis was not altered after six weeks of dicoumarin therapy.

Dr J. F. Biehn cooperated in this work and the Abbott Laboratories supplied the dicoumarin that was used.

From the Department of Surgery, University of Buffalo School of Medicine and the Surgical Service of the Edward J. Meyer Memorial Hospital.

Read before the Section on Pathology and Physiology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

CONTRAINDICATIONS

Dicoumarin should be used with caution or not at all in cases in which ulcerating or granulating lesions are present. In 2 out of 4 cases of inoperable carcinoma of the stomach in which dicoumarin was given hematemesis developed. One of them terminated fatally. Two patients with granulating areas being prepared for skin grafting bled from these areas.

Debilitated and cachectic patients had a more prolonged and severe elevation of the prothrombin time than did more vigorous patients.

Twenty hippuric acid liver function tests were done on patients who had received the drug for the most part for a period of a month. Eighteen of these patients showed a normal excretion of hippuric acid. Only 2 showed an excretion less than the expected normal.

SUMMARY

1 Three hundred mg on two successive days is the suggested basic dose for the prophylactic oral use of dicoumarin.

2 Dicoumarin compound is valuable in the treatment of thrombosis and embolism. Its effect should be maintained for at least four weeks.

Chart 2—Effect of dicoumarin on prothrombin time (normal equals 16 seconds). Solid line curve produced with 300 mg dose given orally daily for first two days. Broken line curve produced with 300 mg the first day, 200 mg the second day and 200 mg the fourth day.

3 Dicoumarin compound should be used with caution or not at all in cases in which there are ulcerating lesions.

ABSTRACT OF DISCUSSION

DR ALTON OCHSNER, New Orleans. As clinicians we are certainly indebted to any substance that will lower the incidence of postoperative thrombosis. The greatest use we can derive from dicoumarol and heparin is not in the treatment of thrombophlebitis but in its prevention. We have learned to appreciate the value of prevention in postoperative thrombosis but, once thrombosis has occurred, we feel that the anticoagulants have little place. As a matter of fact, I fear that if we pay too much attention to the use of anticoagulants for patients with intravascular clotting we are going to allow those patients to develop emboli. After the thrombus has once occurred relatively little can be accomplished by giving anticoagulants. The only thing one can hope to do is to prevent further propagation of the clot. In such an instance it is necessary if the patient has a phlebothrombosis, which we like to differentiate from a thrombophlebitis, the former being a condition in which there is a coagulation not associated with an inflammation of the vein, as has been emphasized by Dr Allen of the Massachusetts General Hospital and his associates, to determine by phlebography the location of the thrombus and to tie off that vein above the site of the thrombus or at least do a phlebectomy. If that is not done these patients are likely to develop emboli. I have seen 1 patient who had five nonfatal emboli in the course of four weeks, during which time he was getting heparin. The question arises as to whether we are justified in giving dicou-

marol and heparin to all patients. Obviously we cannot do it with heparin, because it is too expensive. I doubt if it is necessary to give dicoumarol to all patients. If a patient gives a history of a previous thrombosis or thrombosis in members of his family, it is desirable to give dicoumarol or heparin prophylactically. After the thrombosis has occurred, other measures should be instituted, largely mechanical means, to prevent the loosening of the clot, and if we place too much dependence on the anticoagulants, such as dicoumarol and heparin, we are going to lose some patients from the mechanical breaking off of the emboli.

APPENDICITIS IN CLEVELAND

RALPH M. WATKINS, MD
Chairman, Survey Committee
CLEVELAND

The study of acute appendicitis, unperforated and perforated, has been conducted by a group of us¹ since the autumn of 1939 by means of a survey of cases in metropolitan Cleveland from Jan. 1, 1930 to Jan. 1, 1942. In those twelve years there occurred 19,401 instances of the affliction in this area, which corresponds to all Cuyahoga County, in which Cleveland is located.

The case records are drawn from the sixteen largest hospitals in the county, and these represent the great majority of all hospital beds in the community.

Diagnosis of the condition in each case is based on the pathologist's report. We did not attempt to analyze any records in which chronic appendicitis or anything similar appeared because of disagreements of criteria. Therefore in this report the cases are grouped under one of three headings: (1) acute simple appendicitis, unperforated, (2) perforative appendicitis with peritonitis and (3) perforative appendicitis with abscess.

A great deal of work has been done for several years in Cleveland as in the rest of the country in educating the layman regarding the dangers of appendicitis. Also much effort has been expended in improving surgical methods and preoperative and postoperative care. We have seen a decline in mortality from the aforementioned classifications of appendicitis from 6.8 per cent in 1930 to 2.8 per cent in 1941. We believe that the aforementioned educational efforts are responsible for this gratifying result.

AGE INCIDENCE AND MORTALITY

As is usual, we found few patients among infants and the aged, but high mortalities in these groups. One and five-tenths per cent of the patients were less than 5 years of age but with a death rate of 17 per cent. One and nine-tenths were over 70, with a mortality rate of 34.8 per cent. However, 15.4 per cent were between the ages of 20 and 25, with a death rate of 1.8 per cent. The complete picture is as follows:

From 0 to 9 years of age, 8.6 per cent of all patients, 8.1 per cent died.

Sponsored by the Cleveland Academy of Medicine and the Cleveland Foundation.

Because of lack of space this article is abbreviated in THE JOURNAL by omission of the tables. The complete article appears in the author's reprints.

The survey has profited greatly by the gratuitous labors of Mr. Howard Whipple Green of the Cleveland Health Council, who has done an enormous bulk of work in analyzing our statistics and those of Dr. Bruno Gebhard, director of the Cleveland Health Museum, who has designed our exhibit for the scientific sections of the 1941 and 1942 annual sessions of the American Medical Association.

The following physicians have been members of the Survey Committee representing sixteen greater Cleveland hospitals: Drs. D. C. Darragh, R. M. Hosler, H. H. Pevsner, J. D. Brett, J. H. Lazzari, C. W. Rottler, S. J. Restifo, H. R. Hathaway, W. A. Boukalik, John Kelker, John Renshaw, A. F. Sydnor, B. B. Larsen, J. M. Rossen, John Budd, S. L. Feldman, R. J. McNamee, P. L. Suhay, George Crile, Jr. and Fred Kelly. These persons have done the extracting of case records and have served without compensation.

From 10 to 29 years of age, 57.4 per cent of all patients, 21 per cent died

Thirty years and over, 34.0 per cent of all patients, 8.6 per cent died

With regard to delay and mortality our findings were the usual ones (table 2)

INCIDENCE OF THE DISEASE

The disease is on the increase in this section. In 1930 1 person in 832 suffered from it. There has been a gradual increase, figured on population estimates year by year, until, in 1941, 1 in 653 was a victim. The percentual yearly rates from 1930 to 1942 have been 0.12, 0.12, 0.12, 0.12, 0.13, 0.13, 0.13, 0.14, 0.14, 0.14, 0.13, 0.15

LESSENED DELAY IN OPERATION

One of the important reasons for the great decline in mortality is the result of education of the public. The women delay their operations so much less that we are meeting fewer cases of peritonitis and abscess and more cases of simple acute appendicitis. This is explained in table 3.

CHANGES IN TYPES OF ANESTHETICS

In 1930 93.5 per cent of the patients received some type of general anesthetic, in 1941 only about 68 per cent were given this. In 1930 only 5 per cent were given spinal anesthesia, in 1941 31 per cent received it. Through the twelve years fewer than 1 per cent were given strictly local anesthesia. Our mortality rates were as follows: for general anesthesia 4.5 per cent, for spinal 5.7 per cent, for local 21.0 per cent. The latter was used only in the worst risks. It is interesting to note the trend in methods, but no conclusions are to be drawn as to the effect on our declining mortality.

DECLINING DRAINAGE IN ACUTE AND PERITONITIS TYPES

We are certain that one of the greatest causes for lowered mortality is the change in the practice of drainage.

It is difficult to believe that in 1930 intraperitoneal drainage was done in 29.8 per cent of the acute simple cases. In that year death occurred in 1.4 per cent of simple cases. So much improvement has occurred that in 1941 drainage was done in only 7 per cent and deaths occurred in 0.3 per cent. Drainage is still done in far too many cases and we hope that the figures will decline rapidly.

In peritonitis the surgeons are using less drainage also. In 1930 drainage was done in 94.9 per cent of these cases, and 22.2 per cent of cases of peritonitis were lost. In 1941 drainage was done in 76.1 per cent and the mortality rate was down to 12.2 per cent. Obviously many peritonitis victims will require drainage, but from the figures it is apparent that as time goes on fewer do. This is perhaps the result of less delay in operation with less extensive involvement of the peritoneum. We hope that in the future there will be less delay, fewer cases of severe peritonitis and consequent less mortality.

Obviously, drainage is done in nearly every case of abscess.

Over the twelve year period drainage was done in 2,301 simple cases with a mortality of 2.7 per cent, drainage was not done in 12,138 simple cases with a mortality of 0.55 per cent. Drainage was done in 2,826 cases of peritonitis with a mortality of 19.6 per cent, drainage was not done in 375 cases of peritonitis with a mortality of 10.9 per cent.

CHANGE IN ECONOMIC STATUS

We have observed definitely that charity patients delay operation an average of twelve hours longer than private patients. Our twelve year death rate of charity patients is 6.5 per cent and for private ones 4.3 per cent, because of this delay. However, there are now fewer charity and more of the private group. This accounts in good part for our decline in mortality. In 1930, 77 per cent were private patients and in 1941, 85 per cent. During the depths of the depression, private patients were down to 71.3 per cent in 1933. There is a corresponding decrease in charity patients from as many as 28.7 per cent in 1933 to 15 per cent in 1941.

THE USE OF THE MCBURNEY TYPE INCISION

Our group is of the opinion that the increased use of the McBurney incision has helped to lower our mortality, because the mortality with its use is much lower than that with other types of incision. This has been true through the twelve years. In 1941, as an example, the death rate with the McBurney type was only half that of other types.

The increase in its use is represented by these figures. In 1930 in 50.3 per cent of the patients the surgeons used this incision. There has been a steady increase, until in 1941 it was employed in 67 per cent of the cases.

ABSCESS APPENDIX REMOVED AND NOT REMOVED

Over the twelve years in 1,547 cases the appendix was removed at first operation with 12.7 per cent deaths. In 131 cases only drainage was done and the appendix was left in to be removed later. The mortality rate was 11.4 for the primary operation.

THE USE OF SULFONAMIDE DRUGS

We are inclined merely to report our experience with the sulfonamide drugs without drawing any conclusions because our series is made up of too few cases. The sulfonamides have been highly recommended a number of times by others and are without doubt of great value. The drugs were used during the years 1940 and 1941 in all the case types, but in simple acute appendicitis and cases of abscess they were used in too few instances to be worth reporting. The great interest in the use of them is in peritonitis. In 1940 it was not the custom in Cleveland, at least, to use them in peritonitis in any but a general way, that is, by mouth or hypodermically, and even by these means in only about a third of the cases. In 1941 they were used diversely (table 4). These figures are hardly a recommendation for their use, but we wish to state clearly that we were making no special study of the sulfonamides and the report of their use is only incidental to the complete report. Further, there are too few patients involved for it to be profitable for us to make a study of the extent and severity of their infections.

We hope later to have the necessary financial assistance to enable us to publish in complete detail the complex master charts and maze of figures which are the groundwork of the report. When such time arrives they will be available to those students of the disease who may be interested.

SUMMARY

This report consists of the facts gleaned from a study of 19,401 cases of acute unperforated (simple) and perforated (peritonitis and abscess) appendicitis which occurred in greater Cleveland for the years 1930-1941.

inclusive. They are based on the pathologic diagnosis and collected from sixteen hospitals and represent nearly all the cases of the disease in that time in this area.

CONCLUSION

Certain facts can be learned from the report. Some are well known. Others are important because they represent reasons why our mortality rate has decreased from 68 per cent to 28 per cent in twelve years for the types included in the study.

1 Appendicitis is uncommon but highly fatal in the very young and the very old.

2 The longer operation is delayed the higher the mortality.

3 The disease is on the increase in Cleveland.

4 There is a great increase in the use of spinal anesthesia.

5 The removal or nonremoval of the organ at primary operation for abscess is not of great importance as far as our mortality rate shows.

6 Sulfonamides have been used in too few cases to reveal conclusive results in this series. Other workers have proved them to be of great value.

As definite reasons for the great decline in mortality in this series we add the following facts:

7 There is less delay in operation. This is the result of popular and professional education.

8 A gratifying decrease in drainage, especially in acute cases with perforation, is taking place. This trend should continue.

9 More private and fewer charity patients means that part of our good fortune is due to improved economic conditions.

10 The use of the McBurney type incision results in a lower mortality and we are glad to see that its use is on the increase.

Clinical Notes, Suggestions and New Instruments

RENAL ISCHEMIA PRODUCED BY ANEURYSM OF ABDOMINAL AORTA

BYRON J. HOFFMAN, M.D., EMORY UNIVERSITY, GA.

The experimental investigations of Goldblatt and his associates¹ on dogs in producing renal ischemia and an accompanying hypertensive vascular disease, either benign or malignant have facilitated a better correlation of pathologic conditions observed in man in which renal ischemia has been produced by involvement of or alterations in the renal artery. The initial studies on experimental hypertension by Goldblatt and his co-workers demonstrated that constriction of the main renal artery of one kidney was followed by an elevation in blood pressure, which usually, but not always, returned to normal within four to eight weeks unless the artery to the other kidney was constricted or the other kidney removed.

However, a few cases of hypertension in man have been observed and reported in which a constricting lesion of one renal artery has apparently been responsible for the coexisting hypertensive vascular disease. Hypertension has been reported

in unilateral atherosclerotic narrowing² and embolism³ of the main renal artery, in an aneurysm⁴ of the main renal artery, in a dissecting aneurysm of the abdominal aorta with partial occlusion of the renal artery, in a tumor of one kidney⁵ with compression of the renal artery and in unilateral pyelonephritis⁶ in which the hypertension was partially or completely relieved by removal of the diseased kidney.

The following case is reported because the disease process, which was a saccular aneurysm of the abdominal aorta, produced in man a condition similar to the procedure applied experimentally to animals by Goldblatt and found to be one of the factors responsible for hypertensive vascular disease. The report of a similar case cannot be found.

REPORT OF A CASE

History.—A Negro aged 28 first noticed shortness of breath on exertion during the first part of 1938. This gradually increased in severity and was accompanied by exacerbations of coughing and palpitation. By summer, pedal edema was noted. During the next few months his abdomen gradually increased in size and added to his respiratory difficulty. Because of this dyspnea he could not sleep unless he was propped up in bed or sitting a chair. He was admitted to the Grady Hospital Emory University division, in December.

His past history was not remarkable. He had been in good health until the onset of dyspnea. A review of the systems was negative except as stated in the present illness.

Physical Examination.—The patient was dyspneic even when propped up to the sitting position. The blood pressure was 190 systolic and 117 diastolic in both arms, pulse rate 100, respiratory rate 28 and temperature 98 F. The pupils were round and equal and reacted to light and in accommodation. The retinal arteries were irregularly constricted and had an increase in light reflex and an arteriovenous ratio of 2 to 3. There were no hemorrhages, exudates or edema of the fundi. The teeth were decayed, the gums dirty and the tonsils slightly enlarged and hyperemic. The neck veins were decidedly distended. Moist rales were present throughout the lungs but were more numerous in the base of each lung. The apex beat was diffuse, being in the fifth and sixth intercostal spaces 10 cm to the left of the midsternal line. The tones were poor and a soft systolic murmur was present in the mitral area. The abdomen was greatly distended and dull to percussion and gave a positive fluid wave. The lower extremities had 2 plus pitting edema.

Laboratory Results.—The red blood cell count was 4,710,000 per cubic millimeter with 13 Gm of hemoglobin per hundred cubic centimeters. The white blood cell count was 10,650 with 82 per cent neutrophils and 18 per cent lymphocytes. The sedimentation rate was 25 mm by the Westergren method. The urine contained a trace of albumin and an occasional pus cell. The blood nonprotein nitrogen was 40 mg per hundred cubic centimeters, creatinine 25 mg and sugar 76 mg. The serum albumin was 29 Gm and the globulin 29 Gm with a total serum protein of 58 Gm. The blood Kahn and Wassermann reactions were positive.

A diagnosis of syphilis with hypertensive heart disease and congestive failure was made. Three thousand cc of clear slightly yellow fluid was removed from the abdomen by paracentesis. The patient was placed on routine treatment for congestive heart failure, was digitalized and was given a high protein diet and antisyphilitic treatment in the form of weekly

injections of bismuth and potassium iodide by mouth. He was dismissed from the hospital greatly improved and advised to continue his newly acquired routine.

Course.—The improvement lasted for several months. During April his symptoms of congestive heart failure returned and fluid began to accumulate within his abdomen. He was readmitted to the hospital on March 15, 1939 and 4,000 cc of clear fluid was removed by paracentesis. His blood pressure was 170 systolic and 128 diastolic. He was allowed to go home on March 20 but returned on April 6. Another paracentesis yielded 6,000 cc of fluid.

The symptoms and evidence of congestive heart failure became progressively worse and he was rehospitalized on April 17. The blood pressure at this time was 190 systolic and 110 diastolic, temperature 97 F, pulse rate 95 and respiratory rate 24. A severe generalized anasarca was present. Examination of the fundi revealed slight edema of the retina, with grade 2 to 3 generalized arterial constriction and an arteriovenous ratio of 2 to 3. The lungs contained numerous moist rales, the heart tones were poor without murmurs and the left border of cardiac dullness extended 12 cm to the left of the midsternal line. There was a 4 plus ascites and severe edema of the lower extremities.

The erythrocyte count was 4,100,000 per cubic millimeter with 10 Gm of hemoglobin, the leukocyte count being 9,350 per cubic millimeter with 94 per cent neutrophils and 6 per cent lymphocytes. The urine contained 3 plus albumin, numerous red cells, a few pus cells and numerous hyaline and granular casts. The blood nonprotein nitrogen was 42 mg per hundred cubic centimeters. Paracentesis yielded 6,000 cc of clear fluid. Reaccumulation of this fluid was rapid and the condition of the patient rapidly became worse, with death occurring on April 24, 1939.

POSTMORTEM EXAMINATION

The abnormal feature on external examination was generalized anasarca. The edema of the face was confined mainly to the periocular subcutaneous tissue. The abdomen was distended with fluid and each flank bulged. There was a 2 plus edema of the sacrum, external genitalia and lower extremities.

The left pleural cavity contained about 600 cc and the right 900 cc of clear, slightly yellow fluid having a specific gravity of 1.009. The left lung weighed 520 Gm and the right 750 Gm. Each on cut section was wet and contained small localized areas of bronchopneumonia in the posterior inferior portions.

The pericardial cavity contained 80 cc of clear yellow fluid. The left ventricle of the heart was enlarged to the left. The emptied heart weighed 475 Gm. The left ventricular cavity was dilated and the myocardium soft and atonic to palpation. The left ventricular wall averaged 1.9 cm in thickness and the right 0.4 cm. The valves were normal. The ascending portion of the aorta and the area around the coronary ostia showed a longitudinal tree bark wrinkling characteristic of syphilitic aortitis. The coronary ostia appeared to be slightly but distinctly narrowed by the aortitis.

The abdominal cavity contained approximately 5,000 cc of clear yellow fluid with a specific gravity of 1.012. The inferior edge of the liver was rounded and the hepatic parenchyma had a nutmeg appearance and bulged beneath the cut capsule. The gallbladder wall was moderately edematous. The spleen weighed 160 Gm and contained numerous old fibrous adhesions over the lateral surface that were attached to the parietal peritoneum. The walls of the gastrointestinal tract were slightly edematous.

Bulging from the retroperitoneal region just to the left of the midline and below the level of the celiac artery was a mass measuring 6 cm in diameter. On further exploration this mass was found to be a saccular aneurysm of the posterolateral portion of the abdominal aorta. It was so located as to have become wedged between the abdominal aorta and the left kidney, thereby pushing the left renal artery and vein anteriorly and inferiorly. This is shown in the illustration. In this way the renal vessels were stretched and compressed sufficiently to diminish the lumen of the renal artery considerably. There was no erosion of the renal vessels or of the wall of the aneurysm. About one half of the aneurysm was filled with old organized blood clot.

The left kidney weighed 80 Gm and on cut section was very red. The capsule stripped with difficulty, leaving a fine granular surface. The cortex averaged 4 to 5 mm in thickness and the parenchyma 1.5 cm. In contrast, the right kidney weighed 180 Gm and the capsule stripped with ease, leaving a smooth and glistening surface. The entire parenchyma on cut surface was pale, the cortex averaged 0.9 cm in thickness and the entire parenchyma 3 cm in thickness. The calices, pelves and ureters of the two kidneys were normal. The urinary bladder was normal and there was no obstruction to or in the urethra.

Microscopic Examination.—Sections of the lung revealed a diffuse dilatation and engorgement of the alveolar capillaries, scattered areas of intra alveolar edema, numerous pigment laden phagocytes and a few areas of bronchopneumonia.

Heart sections showed a moderate hypertrophy of the individual muscle fibers, a few small areas of interstitial fibrosis and a moderate degree of diffuse round cell infiltration beneath the epicardium.

An extensive perivascular round cell infiltration was present throughout the sections of the ascending aorta. The media had very little scarring until the region of the coronary ostia.

Position and relative size of the aneurysm and the kidneys

was reached, but at this site there was a high degree of fibrosis and perivascular infiltration. The sections through the abdominal aneurysm showed a definite intimal thickening, an extensive fibrous tissue replacement of the media and a decided perivascular round cell infiltration throughout the entire wall. The walls of the vasa vasorum were very prominent because of their thickness with almost complete obliteration of the lumens.

The liver was normal except for a high degree of passive congestion.

The capsule of the pancreas showed considerable perivascular and perilymphatic infiltration. The endothelium of the smaller arteries and arterioles in this area appeared greatly swollen. Many of the arterioles in this section had a moderate degree of subendothelial hyaline thickening.

The spleen had a slight degree of sinusoidal congestion and a moderate intimal thickening of the central arterioles.

The two kidneys differed greatly in microscopic structure. The left had a capsule distinctly thickened with fibrous tissue and several small but prominent arteries in the outer portion. Dilated and engorged capillaries were prominent in the deeper portions and some old blood pigment was scattered throughout the fibrous capsule. The cortex was striking because of the diffuse and severe atrophy of the convoluted tubules. In places many of the atrophic epithelial cells of the convoluted tubules appeared to have undergone a moderate degree of

natty degeneration. The glomeruli appeared numerous because of the extensive tubular atrophy. Many were completely replaced with hyaline material or had varying degrees of fibrous thickening of Bowman's capsule. All glomerular tufts were diffusely hyperemic and possessed a cellular appearance because of slight proliferation of the capillary endothelium and epithelium. There was also a slight to moderate increase in the basement membrane hyalin. Throughout the cortex and medulla there was a diffuse and severe capillary dilatation and engorgement with erythrocytes. The smaller arteries and arterioles were readily identified because of the thickened media. The interlobular arteries were normal, and there was no subendothelial increase of hyalin in the intima of the terminal arterioles. Albumin filled many of the tubules. A few aggregations of round cells were scattered throughout the cortex. Some of this infiltration was distinctly perivascular.

The right kidney differed greatly from the left. The capsule was thin. The outstanding feature of the cortex was the diffuse and severe dilatation of the convoluted tubules. A few scattered wedge-shaped areas of scarring were present at the periphery of the cortex. The glomeruli were replaced with fibrous tissue and hyaline material and the surrounding tubules were atrophic. An occasional arteriole would show a greatly thickened muscle wall and narrowed lumen. All glomeruli were large. The tufts were large and cellular and had a slight proliferation of the capillary endothelium and epithelium without an increase of intracapillary or intercapillary hyalin. In places the capsular epithelium had undergone sufficient proliferation to form a small crescent. There was no engorgement of the glomerular or interstitial capillaries. A few of the collecting tubules contained red cells, leukocytes or protein material. The large interlobular and small arteries and arterioles were normal except for the arterioles mentioned in the wedge shaped atrophic and scarred areas in the outer portion of the cortex.

COMMENT

The unusual location and the progressive enlargement of the abdominal aneurysm so as to cause an increasing amount of pressure on the left renal vessels offer a condition in man similar to Goldblatt's experimental work on animals. The clinical course of this patient was rapid. Even though the hypertension was severe with a very high diastolic reading and the patient was in his late twenties there were never the proper eye-ground changes and urinary conditions to indicate a malignant nephrosclerosis. Arteriolonecrosis was not found on microscopic study of the sections taken at autopsy. The immediate cause of death was myocardial failure rather than renal insufficiency. The compensatory efforts of the right kidney were apparently physiologically adequate. The slight retention of nonprotein nitrogen material is consistent with a definite passive congestion rather than a primary renal failure.

The syphilitic aortitis with the slight narrowing of the coronary ostia may have prohibited a greater degree and longer period of compensatory myocardial hypertrophy.

The outstanding feature of the ischemic kidney was the uniform and diffuse atrophy of the nephron unit along with the severe dilatation and engorgement of the glomerular and interstitial capillaries with red cells. The latter accounted for the red appearance noted grossly and can probably be attributed to the venous obstruction caused by compression of the renal vein rather than an inflammatory process. The unusual number of small arteries and the dilated capillaries in the thickened capsule suggest an attempt to establish collateral circulation.

In the right kidney the endothelial and epithelial proliferation of the glomerular tufts and the crescent formation were unaccompanied by other features of glomerulonephritis and were therefore attributed to the proliferation accompanying the compensatory efforts of the right kidney.

SUMMARY

A Negro aged 28 had a saccular aneurysm of the abdominal aorta, syphilitic in origin, which compressed and narrowed the lumens of the left renal vessels. This was accompanied by hypertensive vascular disease and reproduced in man the ingenious experimental work done on dogs by Goldblatt.

Special Article

HANDBOOK OF NUTRITION X

THE FAT SOLUBLE VITAMINS

HUGH R. BUTT, M.D.

ROCHESTER, MINN.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

An attempt has been made in the present review to outline a few known facts about each fat soluble vitamin and to mention the most recent advances of general interest that have occurred since publication of the symposium on vitamins sponsored by the American Medical Association in 1939. No attempt has been made to delve into many of the details in this field, rather, data have been presented which it is hoped will be of value in orienting conceptions in a rapidly changing subject.

VITAMIN A

CHEMISTRY AND PHYSIOLOGY

The chemistry and physiology of vitamin A and substances having vitamin A activity have been considered in some detail in previous reviews in *THE JOURNAL*.¹

Evidence reveals that there exists, in addition to vitamin A, another compound which has been designated as vitamin A₂. In chemical structure vitamin A₁ is related closely to vitamin A₂, biologically the activity is the same. It appears that vitamin A predominates in the tissues of salt water fish and that vitamin A₂ predominates in the tissues of fresh water fish. The absence of vitamin A₂ in the liver of mammals and other land animals probably can be explained by the absence of vitamin A₂ in their food.

Vitamin A is a fat soluble compound. Apparently, its absorption is facilitated greatly by the simultaneous absorption of a certain amount of fat. Most investigators agree that the presence of bile is not necessary for proper absorption of vitamin A, however, it still is good therapeutic practice to administer bile salts with concentrates of vitamin A in the treatment of patients who have obstruction of the biliary tract. Esters of vitamin A apparently behave in the intestinal tract in a manner similar to the esters of other fatty acids. Apparently they are hydrolyzed by the enzymes present, and during the height of absorption the vitamin exists in the intestinal wall chiefly as an alcohol.²

The precursors of vitamin A are all the carotenoid pigments commonly called carotene. Since most of vitamin A comes in the form of carotene, some knowledge of its metabolism is important.

Carotene is absorbed less readily than vitamin A and is subject to several more hazards than vitamin A.

Carotene apparently requires for its absorption the presence of bile in the intestinal tract. In those conditions in which bile is excluded completely or partially from the intestinal tract or whenever there is a deficiency of bile salts, bile must be given as a supplement in order to assure proper absorption. It also has been demonstrated⁴ that liquid petrolatum can seriously inhibit absorption of carotene. For this reason, liquid petrolatum should not be given immediately after meals.

Storage—After absorption, the greater portion of carotene is held in the liver, where it gradually disappears. In the Kupfer cells is the concentration of vitamin A in the liver increases. In the case of human beings the content of vitamin A, as in all animals, is much lower in the liver at birth, irrespective of the diet of the mother, than in the liver of a normal adult. The liver probably stores about 95 per cent of the reserve of vitamin A in the body and the amount stored is, as a rule, less during childhood and gradually increases with age.⁵ The exact mechanism by which vitamin A is called forth from its reserve store is not known, but from several sources it appears that the distribution of vitamin A in the circulating blood and tissues is controlled in part by the nervous system.⁶

Excretion—Neither carotene nor vitamin A is excreted by the kidneys unless an excessive dose of either of these substances has been administered. Carotene is readily excreted in the feces but vitamin A is excreted much less readily. Apparently, unutilized excesses of carotene and vitamin A find other channels of excretion or are destroyed in the intestine or elsewhere.

Human milk contains both carotene and vitamin A. The colostrum of the human breast has from two to three times the biologic activity of vitamin A of early milk, and early human milk has from five to ten times the biologic vitamin A activity of cow's milk. Apparently the biologic activity of vitamin A of early human milk is not increased by supplementary administration of cod liver oil to the mother.

It formerly was believed that vitamin A produced a profound effect on the nervous system. However, Wolbach and Bessey⁹ have now shown that in vita-

min A deficiency in rats, skeletal growth is retarded earlier than that of the soft tissues in general, including that of the central nervous system, and that at least in the white rat the nervous manifestations are due to pressure effects caused by relative overgrowth of the central nervous system.

SOURCES, HUMAN REQUIREMENTS AND TOXICITY

Vitamin A is rather widespread in nature in the form of its precursors, the yellow and red carotenoid pigments (provitamins). These pigments are found in the plant world, being distributed from bacteria to garden fruits and vegetables. Pigments, of course, are found chiefly in association with chlorophyll and in the green leaves of plants, this is not invariably true, however, since carrots and sweet potatoes, which are yellow, also are rich in these substances. A few of the more important and rich sources of vitamin A and carotene are green leaf vegetables, green snap beans, spinach, carrots, peas, asparagus, yellow vegetables, eggs, whole milk and whole milk products and apricots.

Vitamin A is fairly stable to heat but is destroyed by oxidation. Foods that are heated for long periods may reveal a rather large loss of potency in vitamin A. Since activity of the vitamin is not affected by boiling, foods cooked in this manner retain their potency. Canned foods and foods stored in the frozen state maintain their maximal value of vitamin A, dried and dehydrated foods, however, show considerable loss.

Human Requirements—Vitamin A is essential for normal metabolism. Although the exact minimal requirement of vitamin A for man is still unknown, considerable work has been carried out in an effort to settle this point.¹⁰ Since the recommended daily allowances for definite nutrients as defined by the Food and Nutrition Board of the National Research Council and later adopted by the Council on Foods and Nutrition of the American Medical Association represent the thoughts of the leaders in these particular fields, it would seem well that these should be accepted without considering other work in this field in any detail.

For the average man and woman of 70 Kg and 56 Kg respectively, the daily allowance is 5,000 international units. In the latter half of pregnancy, 6,000 international units is required, and during lactation 8,000 international units. For children aged less than a year, 1,500 units is required, for those aged 1 to 3 years, 2,000, for those from 4 to 6 years, 2,500, for those from 7 to 9 years, 3,500, and for those from 10 to 12 years, 4,500. For children more than 12 but not more than 15 years of age, 5,000 units is required, and for those from 16 to 20 years of age, 6,000 units. Allowances in all these instances may be less if provided by vitamin A and greater if provided chiefly by the provitamin carotene.

Toxicity—It is extremely difficult to evaluate the few reports concerning the injurious effects on man following ingestion of cod liver oil. Owing to the general favorable clinical experience obtained in the use of cod liver oil and other preparations containing vita-

min A, extreme care must be taken to be certain that cod liver oil is harmful before its administration is discontinued. Administration of from 50,000 to 300,000 or more U S P units of vitamin A daily for as long as two to six months or more has not been followed by any harmful effects.¹¹

EFFECT OF DEFICIENCY OF VITAMIN A

In Relation to Infection—Few investigators doubt that severe deficiency of vitamin A, or any vitamin, will lower resistance to infection, and almost all will agree that administration of vitamin A during the course of any infection will have little beneficial effect on the outcome unless such a deficiency is present. Some workers believe that the frequency and high mortality rate in pneumonia of infants who are deficient in vitamin A result from a disturbance of function of the mucosa of all parts of the lungs. Others believe that administration of vitamin A in large amounts is beneficial in preventing common infections of the respiratory tract. This subject, however, is in general extremely controversial. Enough evidence indicates that there are many other factors of equal or greater influence in infection than vitamin A and that there is no justification for calling vitamin A the "anti-infection vitamin."

Ocular Changes—That night blindness is directly related to poor nutrition has been recognized for some time. Experimentally it is now established that vitamin A is the precursor of visual purple as well as the product of its decomposition. Apparently vitamin A unites in the retina with a protein to form visual purple. This, of course, takes place continuously and depends on a sufficient supply of vitamin A. Exposure of the retina to light leads to a chemical change which is reversible but which is not always efficient, and therefore needed supplies of vitamin A must always be available. Not only does vitamin A play a part in metabolism of visual purple (rhodopsin), but it is also important in the formation of visual violet (iodopsin), which is present in the retinal cones.¹² Not only does deficiency of vitamin A produce night blindness but, experimentally, it has been demonstrated that severe deficiency of vitamin A may result in structural breakdown of the retina itself.¹³ Night blindness, as recognized clinically, perhaps is associated most frequently with cirrhosis of the liver,¹⁴ gastrocolic fistula¹⁵ and forms of severe chronic diarrhea.

It has been thought that night blindness was one of the earliest symptoms of deficiency of vitamin A, but Kruse¹⁶ suggested recently that even earlier changes of deficiency may be detected by biomicroscopic examination. In a study of 143 persons in the low income group it was reported that 45 per cent had gross and 54 per cent had microscopic ocular lesions (xerosis conjunctivae) characteristic of avitaminosis A. It also was suggested that xerosis conjunctivae probably precedes night blindness as an early sign of deficiency of vitamin A. Kruse suggested that this condition is prevalent in the population at large, and he also pointed out that a vascular reaction of the eyes of these patients is

distinct from that noted as a result of deficiency of riboflavin. Others¹⁷ have reported that follicular conjunctivitis occurring among children apparently is a result of deficiency of vitamin A. These workers pointed out that the administration of from 25,000 to 38,000 U S P units of vitamin A daily did not result in any more rapid healing than if only 15,000 U S P units had been given. Apparently, in treatment of conditions with vitamin A, a time factor operates which limits the rate of healing of a lesion. Apparently excessive intake of vitamin A does not increase this rate proportionately.

Epithelium—Dryness and scaliness of the skin are perhaps some of the earliest manifestations of involvement of the skin resulting from deficiency of vitamin A. Within the past few years several investigators have reported cases in which cutaneous lesions were present and which were considered the result of deficiency of vitamin A.¹⁸ One type of lesion is characterized by small pustules which appear around the hair follicles or extensor surfaces of the upper and lower extremities, on the shoulder and on the lower part of the abdomen and buttocks. These pustules vary in diameter up to 5 mm, are hard and deeply pigmented and have a surrounding zone of deep pigmentation. An epithelial plug is in the center of the lesion which, when expressed, leaves a crater. Other writers have described a type of lesion which resembles in many ways the pustule of acne, with the exception that pustulation is uncommon. It is believed¹⁹ that keratosis pilaris, ichthyosis follicularis and other synonyms are descriptive terms for the cutaneous manifestations of deficiency of vitamin A. In treatment of such conditions daily doses of 100,000 to 300,000 international units of vitamin A is given for two or three months before beneficial effects are noted. It is pointed out that response of cutaneous lesions to vitamin A is slow, depending as it does on anatomic repair.

Recently²⁰ evidence has been reported which indicates that vernix caseosa is a manifestation of deficiency of vitamin A of newborn infants and that it represents disturbances in cornification analogous to the dermal changes noted in other manifestations of deficiency of vitamin A. This work has not yet been confirmed.

A majority of investigators have failed to find any relation between the presence of calculi in the urinary tract and a diet deficient in vitamin A, in spite of suggestive experimental evidence in this direction.²¹

Liver—It has been established that the liver plays a major role in the metabolism of vitamin A, but the exact manner in which this is accomplished is not known. It has been known for many years that keratomalacia and night blindness accompany diseases of the liver, and recently these conditions have been reported²² in association with obstructive biliary cir-

rhosis. Others³ have demonstrated deficiency of vitamin A in cirrhosis of the liver not associated with jaundice. Many others have demonstrated repeatedly that the vitamin A in the liver and blood of patients who have severe hepatic injury nearly always is decreased considerably.⁴ It has been suggested that since pathologic conditions of the liver result in incomplete transformation of carotene into vitamin A, fish liver oil should be given in preference to carotene in the treatment of hepatic disease.⁵

It is obvious that deficiency of vitamin A also may result from poor absorption of the vitamins, such as may occur in diarrhea,⁶ celiac disease,⁷ and various diseases of the liver in which the flow of bile is disrupted.⁸

METHODS FOR MEASURING DEFICIENCY OF VITAMIN A

Dark Adaptation—The fact that night blindness is an early symptom of deficiency of vitamin A led to the development of visual adaptation in dim light as a method for the diagnosis of deficiency of vitamin A. Whether deficiency of vitamin A can be measured by testing adaptation to dark continues to be a most controversial subject. Some contend that this method is satisfactory for measuring deficiency of vitamin A.⁹ Others²⁰ contend that, although some rela-

tion exists between readings of the biophotometer and of nutrition of vitamin A, yet the relation is not close enough to warrant use of the test as a means of diagnosis of subclinical deficiency of vitamin A. It has been pointed out that the method is time consuming, and for this reason alone its routine clinical use practically is ruled out. Certainly, minor fluctuations in dark adaptation in terms of deficiency of vitamin A should receive little emphasis unless the physical methods are used to test the reliability of the differences. It is true that a majority of workers believe that the study of dark adaptation can be used as a test for deficiency of vitamin A, but until differences in technique and in interpretation of results have been resolved it is impossible to be certain how far recorded observations represent physiologic facts. In fact, by placing human beings on a diet deficient in vitamin A over long periods, some investigators²¹ have been unable to produce clinical night blindness or even changes in dark adaptation. It may be, as stated by Josephs,²² that all this discrepancy may be the result of lack of knowledge of methods for determining sufficient storage of vitamin A.

No definite correlation between biophotometer readings and the content of vitamin A in the blood has been observed.²³ Although it has been demonstrated that the amount of vitamin A in the blood is dependent on the amount in the diet, yet evidence as to whether determination of vitamin A in the blood is of value in judging the nutritional status is still contradictory. Recently evidence has been presented which suggests that the concentration of vitamin A in the blood plasma is a considerably more sensitive indicator of deficiency of vitamin A than the dark adaptation.²⁴

The same contradictory evidence is presented for measuring vitamin A by examination of scrapings from the eye and vagina. From all these studies it would be judged that the methods for measuring deficiency of vitamin A of man still are somewhat unreliable and demand further study. Among some physicists and chemists there still is doubt whether the small quanti-

ties of vitamin A present in the blood stream of man can be measured with the chemical methods available. There are others who feel that no satisfactory chemical methods can be developed until the storage capacity of the body for vitamin A can be estimated in some degree.

VITAMIN D

Since the time (1922) of McCollum's demonstration that vitamin D is distinct from vitamin A, this vitamin (D) has received perhaps the greatest universal attention of any. Here, in the early history of nutritional investigation, was found a substance which was of value in the prevention and cure of a disease.

CHEMICAL ASPECTS

Some ten forms of vitamin D are known, but only two of them are of practical importance. One is ergosterol, which on exposure to ultraviolet light becomes viosterol (a name adopted by the Council on Pharmacy and Chemistry of the American Medical Association). The other form of vitamin D of practical use is activated 7-dehydrocholesterol. This substance is present in animal fats and its active form is produced in the skin, feathers or furs of animals exposed to sun light or other sources of ultraviolet waves.³⁹ Successful synthesis of compounds related to the antirachitic vitamin has been reported and it is hoped that a suitable product soon will be available.⁴⁰

PHYSIOLOGIC ASPECTS

The active vitamin D formed in the skin is absorbed by the blood. When the vitamin is ingested it is readily absorbed from the intestinal tract if adequate amounts of bile salts are present. Results of recent investigations indicate that the salts of desoxycholic acid may be particularly concerned with the absorption of the liposoluble vitamins.

The chief storehouse of vitamin D in the human being is the liver, but significant amounts are stored also in the skin, brain, lungs, spleen and bones. Moreover, although the liver is the chief storehouse of the vitamin, normal hepatic function is necessary to promote the antirachitic action of vitamin D.

The body apparently has great powers for the conservation of vitamin D. Studies on the excretion of vitamin D are lacking, but it is known that small doses of vitamin D will exert an influence which endures for several weeks and that large doses of it are carefully preserved for a long time.

Concentration of vitamin D in the blood has been studied inadequately, and in view of methods presently available such studies are impracticable for even a well equipped laboratory to carry out.³⁸

The exact role of vitamin D in the metabolism of calcium and phosphorus still is not fully established. The action of vitamin D on calcium and phosphorus metabolism, however, seems to be concerned chiefly with absorption of the elements from the intestinal tract.

In carefully conducted studies,³⁹ it has been reported that one of the first signs of deficiency of vitamin D is the decrease in the amount of calcium in the urine, followed by an increase of calcium in the stool which progresses with the deficiency until a negative calcium balance exists. The changes in the metabolism of phosphorus differ only in the fact that the urinary excretion of phosphorus is increased. These changes can be reversed with very small doses of vitamin D. Results of other studies tend to confirm these observations.⁴⁰

There exists in the body an enzyme, phosphatase, which is related intimately to phosphorus metabolism. Its exact function in the serum is not known, but in active rickets the value for phosphatase in the serum is high. The administration of vitamin D under these circumstances decreases the concentration toward normal but more slowly than it increases the concentration of calcium and phosphorus.

DISTRIBUTION, HUMAN REQUIREMENT AND TOXICITY

Vitamin D is an essential vitamin but is contained in only a few of the foods in the average American diet. Small amounts are present in eggs, herring, sardines, tuna and salmon, either fresh or canned.⁴¹ Contrary to a popular misconception, butter contains only a very small amount of vitamin D.

Since the average diet furnishes so little vitamin D it must be assumed either that the requirement of vitamin D for man is extremely low or that his needs usually are provided by exposure to sunshine. The requirement of vitamin D during adult life, therefore, remains to be determined. Vitamin D undoubtedly is necessary for older children and adult persons, and when not available from sunshine it should be provided, probably up to the minimal amounts recommended for infants. During pregnancy and lactation and for children under a year of age 400 to 800 international units of vitamin D is the daily requirement recommended by the Food and Nutrition Board of the National Research Council. In administering antirachitic agents the physician should think in terms of units of vitamin D, since this is the only way in which the doses of the various substances containing vitamin D, which differ greatly in volume, can be reduced to a common denominator.

When doses of vitamin D many times the therapeutic dose are administered to animals, certain pathologic changes are noted. In the human being, however, no serious toxic effects have been reported in cases in which doses of as much as 1,000,000 units have been administered to rachitic children.⁴² Some adult persons treated with large doses of vitamin D have complained of nausea, headache, diarrhea, anorexia, urinary frequency and lassitude. If renal insufficiency exists, it might be feared that some degree of toxicity would result from overdosage with vitamin D.⁴³

CLINICAL USE

Little can be added to the comprehensive article by Jeans and Stearns⁴⁴ on the clinical usefulness and available sources of vitamin D which appeared in the symposium on vitamins sponsored by the American Medical Association in 1939. Thus and several other comprehensive reviews⁴⁵ deal most adequately with this problem, and there seems little need of much repetition. Other sections to be presented in this review also will deal with the clinical use and value of vitamin D.

The suggestion made by Park,⁴⁶ however, in the treatment of rickets will again bear emphasis. For preventive measures the importance of commencing administration of the vitamin early and reaching the full dose "certainly by the end of the second month" of the infant's life cannot be repeated too often. In the active treatment of rickets, milk containing vitamin D does not exhibit sufficient activity to end the disease abruptly, and doses of vitamin D sufficient to furnish 1,000 U S P units daily, or even 10,000 to 20,000 units to premature infants, may be required.

The treatment of active rickets with large, single parenteral doses of vitamin D has received considerable attention during the past two years.⁴⁷ Administration of 500,000 to 1,000,000 U S P units of vitamin D to children who had rickets (including premature infants) has been followed by rapid healing without clinical evidence of toxicity.

Many other diseases unrelated to rickets have been reported as benefited by the administration of vitamin D. Pemphigus⁴⁸ chronic ulcers of the extremities⁴⁹ and psoriasis⁵⁰ are only a few conditions reported as benefited thereby. Most of the results reported have not been confirmed.

VITAMIN E

When it is compared to the other vitamins, vitamin E assumes a rather unsatisfactory position, since it has never been demonstrated that a deficiency of this substance occurs in man. As early as 1922 the necessity of this factor (then called "factor X") was recognized in animals, and in spite of a host of brilliant chemical and physiologic discoveries clinical attempts at application of this knowledge have resulted only in controversy.

CHEMICAL AND PHYSIOLOGIC PROPERTIES

Recent advances in the knowledge of vitamin E have been confined in a large measure to the field of chemistry and experimental animal physiology. Details of these advances may be found in journals or books devoted to this subject.¹ Suffice it herein to say that

there are now more than one hundred and thirty compounds which exhibit vitamin E activity. The most active of these compounds are the tocopherols. The tocopherols are readily soluble in lipid solvents, resist high temperatures and lose their activity in the presence of mild oxidizing agents. It has been postulated that in the living organism vitamin E might act as a respiratory enzyme.

In animals a lack of vitamin E manifests itself chiefly by changes which it causes in the reproductive mechanism and in the muscular and nervous systems. In the female rat conception is followed by "resorptive sterility," and in the male rat degeneration of the germinal epithelium and spermatozoa develops to the point of complete loss of reproductive power. Absence of vitamin E in certain animals (rabbits and guinea pigs) is followed by muscular dystrophy and a characteristic paralysis of the hindquarters. In other animals (chicks) cephalomalacia and exudative diathesis may develop.

The possible relationship of vitamin E to the glands of internal secretion and to the growth of tumors has stimulated a great amount of experimental work, but results are completely controversial.⁵²

Several methods exist for the chemical and biologic estimation of vitamin E, but they are of little importance to the clinician.

SOURCES, HUMAN REQUIREMENT AND TOXICITY

Wheat germ oil is the richest source of vitamin E, but this vitamin also is found in considerable amounts in cottonseed oil, lettuce oil, rice germ oil and other seed germ oils. The human requirements of vitamin E are completely unknown.

No toxic reactions have been reported in cases in which small doses were administered, and large doses of wheat germ oil have given rise only to minor symptoms. The danger of the production of neoplasms after the continued ingestion of large doses of tocopherols appears to be nonexistent.

CLINICAL USE

If the physician makes only a cursory appraisal of the current literature he may be led to believe that in vitamin E he has a potent weapon for his attack on habitual abortion, sterility, menstrual disturbances and various myoneurogenic diseases. A critical analysis of these numerous reports, however, tends to stem over-enthusiasm.⁵³

The Reproductive System—A number of papers in which the treatment of habitual abortion with vitamin E is considered have appeared, but when one considers the inherent difficulty of making the diagnosis of habitual abortion, plus the absence of knowledge of the outcome in cases in which treatment is completely lacking, then one is impressed with the almost complete futility of attempting to arrive at any justifiable conclusion. The physician, however, must not become iconoclastic but must keep an open mind on this subject and await results of further study.⁵⁴

Vitamin E has been used in the treatment of various other disturbances of the reproductive system, including male and female sterility, menstrual disturbances, toxemias of pregnancy, faulty lactation and vaginal pruritus. The reported results are at variance and cannot be accepted until further evidence has been accumulated.

Myoneurogenic Disturbances—During the past two years clinicians have concerned themselves with the possible benefit of vitamin E in the treatment of various neuromuscular disturbances. The encouragement aroused by early reports⁵⁵ on the treatment of amyotrophic lateral sclerosis with vitamin E was short lived. More extensive studies soon followed and the results were discouraging⁵⁶ in treatment of both amyotrophic lateral sclerosis and various forms of dystrophy. Wechsler's reports,⁵⁷ however, continue to show favorable results in the treatment of amyotrophic lateral sclerosis. He suggested that the therapeutic doses previously used were too small and implied that 150 to 300 mg given intramuscularly, and 200 mg or more given by mouth, might be an adequate daily dose of alpha-tocopherol.

Since investigation in this field is relatively new, physicians must completely reserve their answer to the question "What can we expect of vitamin E in the treatment of human myoneurogenic disturbances?"

VITAMIN K

In the review of vitamins sponsored by the American Medical Association in 1939, vitamin K appeared under the section entitled "Other factors less well known vitamins." This fact in itself emphasizes how rapid has been the increase in knowledge of this vitamin. In this

brief review no attempt will be made to mention the large volume of literature which has accumulated on this subject during the past three years. For details and an extensive bibliography the reader is referred to recent monographs and reviews on the subject.⁵⁸

CHEMISTRY AND PHYSIOLOGY

Chemistry—In May 1939 McKee and his associates reported the isolation of vitamin K₁ from alfalfa and of vitamin K₂ from putrefied fish meal and presented evidence to indicate a quinoid structure of these vitamins. Independently, several groups of investigators reported the structure of the vitamin K₁ molecule to be 2-methyl-3-plytyl-1,4-naphthoquinone. Vitamin K₂ has not yet been prepared synthetically, nor has its true structure been determined. Both vitamins are fat soluble, and exposure of the pure preparation to sunlight and artificial light results in a loss of the activity of the vitamin. The activity also is destroyed by alkalis and strong acids. Fieser and his associates have investigated nearly every possible modification of the vitamin K₁ molecule, and in every instance the change is attended with a distinct diminution in biologic potency.⁵⁹

Soon after it was demonstrated that vitamin K₁ and K₂ possessed a quinoid structure, other compounds possessing this structure were investigated. It was found that of all the compounds studied 2-methyl-1,4-naphthoquinone (menadione) proved to possess the strongest antihemorrhagic activity. By the chick assay method this compound has been found to be about three times as potent as vitamin K₁, at least on a basis of weight. Menadione is so active that several investigators have suggested that it be adopted as a basic standard assay of vitamin K. Because of the wide usefulness of this compound in clinical medicine, the Council on Pharmacy and Chemistry of the American Medical Association, on the recommendation of the Committee on Nomenclature, authorized menadione as a nonproprietary name for this substance.⁶⁰

Physiology—Pure vitamin K₁ has not been available long enough to allow complete knowledge of its physiologic action to be collected. It has been suggested that vitamin K acts as a reversible oxidation reduction catalyst. It has been suggested that the reversible character of the vitamin may be used to explain the fact that small quantities are effective clinically. It is known, however, that the vitamin is associated in some way with the integrity of the hepatic parenchyma and with the metabolism of prothrombin.

The presence of adequate amounts of bile salts is required for proper absorption of vitamin K. Recently, it has been emphasized that excessive amounts of liquid petrolatum administered with meals may prevent proper absorption of this vitamin. Clinical experience with this vitamin indicates that it is not absorbed through the colon or upper part of the ileum but that it is absorbed readily through the upper part of the jejunum.

The vitamin apparently is not stored easily in the body, and clinical work indicates that what little is stored in the body is in the liver.

So far as is known, vitamin K is not present in the urine but it can be demonstrated in the feces. Whether it is there because organisms are present in the feces which are known to contain vitamin K or whether the presence of the vitamin in feces is referable to real excretion of vitamin K remains to be established.

So far as is known, vitamin K at present has no relation to immunity, infection, pregnancy, lactation or the nervousness associated with diseases of the gastrointestinal tract or cardiovascular system. It is associated intimately, however, with normal physiologic function of the liver and with proper coagulation of the blood. Its exact role in coagulation of blood is not known. Vitamin K is known to be necessary for proper formation of prothrombin but in what manner this is accomplished remains to be determined. A deficiency of vitamin K from any cause produces a deficiency of prothrombin in the circulating blood, and in all instances, except those in which severe hepatic damage is present, this deficiency of prothrombin can be corrected by proper administration of vitamin K or synthetic compounds which possess antihemorrhagic activity.⁶¹

SOURCES, HUMAN REQUIREMENTS AND TOXICITY

Vitamin K is distributed widely in nature, and among its richest sources are green leaves of different kinds. Alfalfa and spinach are rich in the vitamin, and cabbage, cauliflower, carrot tops, soy bean oil and seaweed are all good sources. Less abundant sources are tomatoes, orange peel and hemp seed. Seeds, fruits and roots in general contain considerably less vitamin K than do green leaves of different kinds. Parts of the plant that contain chlorophyll usually have the largest amount of vitamin K. The vitamin also is found in a number of bacteria, and during growth of bacteria the vitamin apparently is synthesized and retained.⁶²

The exact minimal requirements of vitamin K for infant, child, mother or normal adult have not yet been determined. It has been suggested that the requirement of vitamin K for newborn infants is extremely low and that possibly 1 microgram of synthetic vitamin K is a sufficient daily amount. It has been pointed out that there is no relationship between the mother's diet and the postpartum level of prothrombin of newborn infants. Apparently a completely adequate diet for the pregnant woman, as it is understood today, is not sufficient to protect the child from the potential dangers of hemorrhage resulting from a deficiency of prothrombin. It is known, however, that pure vitamin K₁ or a synthetic compound exhibiting vitamin K activity, in doses of from 1 to 2 mg., is capable of correcting deficiency of vitamin K in most instances. This dose, however, apparently depends on the degree of hepatic damage present. It is known that diarrhea and inadequate intestinal absorption will increase the need for vitamin K. This general lack of knowledge of requirements for vitamin K undoubtedly will be corrected as soon as methods are developed by which vitamin K can be measured in biologic material.

Toxicity—To date no serious untoward reaction has been observed among persons who have received reasonable therapeutic doses of either natural concentrates of vitamin K, synthetic vitamin K₁ or any of the synthetic

compounds exhibiting antihemorrhagic activity now available commercially. An effect has not been noted on blood pressure, respiration, permeability of capillaries or urinary excretion following administration of any of these compounds. It has been observed, however, that doses of menadione as large as 180 mg. administered orally to human beings result in vomiting and porphyrinuria. These huge doses, however, are so obviously greater than those employed for therapeutic use that at present it appears safe to continue therapeutic administration of these synthetic compounds. Fieser wisely pointed out that some clinical consideration should be given to the possible conflict or otherwise undesirable characteristics which may be associated with conjugates resulting from administration of menadione. He pointed out that the delayed action of the administered material would appear to be subject to considerable uncertainty, and the wide opportunity for transformation of different types would lead one to expect a variability in the response, depending on the manner of administration and the condition of the patient.⁶³

METHODS FOR MEASURING DEFICIENCY OF VITAMIN K IN MAN: ASSAY METHODS, UNITAGE AND BIOLOGIC METHODS

Like every new vitamin, vitamin K possesses numerous methods of assay and standards of unity. For details of this subject two articles are referred to.⁶³ The wide interest in vitamin K and associated naphthoquinones has given rise to the need for convenient and accurate methods for their estimation. A step in this direction was made by Trenner and Bacher,⁶⁴ who described a method by which many quinone-like substances may be assayed. Others have also recently reported work in this direction.⁶⁵

Of clinical importance are the methods by which deficiency of vitamin K can be recognized by simple laboratory procedures. Several excellent methods for measuring deficiency of prothrombin in the blood of man have been described, but in the experience of many the method developed by Quick and his associates has been found adaptable for general use in the clinical laboratory. The method developed by Warner and his associates also is used with modification in many laboratories.⁶⁶ Details of these methods are given in several publications.⁶⁶

The so-called bedside method has received considerable use and is reported to be of great value for the general practitioner. Suitable compact sets for making this measurement at the bedside are now available commercially.⁶ Several micromethods for measuring deficiency of prothrombin of infants also have been described and are used in many institutions routinely.⁶⁸

It must be admitted that all current methods for the estimation of prothrombin are, of necessity, indirect. However, certain of these methods of measuring prothrombin are the most nearly accurate methods available at present for estimation of the tendency of a patient to bleed in the presence of suspected deficiency of prothrombin. The information afforded by the measurement of prothrombin in the circulating blood is much more nearly accurate in the prediction of the tendency of a patient to bleed than is the measurement of the coagulation of bleeding time as formerly used in the consideration of such tendencies.

CLINICAL USE OF VITAMIN K

Among Adults—A number of conditions have been reported in which a deficiency of prothrombin exists that can be corrected by the administration of vitamin K.⁶⁹ Deficiency of prothrombin among human beings apparently may occur in any of the following circumstances:

1 After ingestion of a diet inadequate in vitamin K. This condition is rare but the clinical observation is well supported by the experimental production of low values for prothrombin in the blood of rabbits and mice following administration of diets deficient in vitamin K.

2 With inadequate intestinal absorption. This may result from (a) lack of bile in the intestine owing to decreased secretion of bile salts, (b) obstruction of the bile duct from any cause or (c) to inadequate absorption attributable to various intestinal lesions, such as intestinal obstruction, and to short-circuiting surgical procedures. It likewise has been demonstrated that severe diarrheal diseases, such as ulcerative colitis, sprue or celiac disease, may result in a deficiency of prothrombin.⁷⁰

3 Injury to the liver. There is, of course, considerable evidence, both clinical and experimental, to indicate that the liver plays an active part in the forma-

tion of prothrombin and that any severe injury to this organ results in a deficiency of prothrombin.⁷¹

The story of deficiency of prothrombin resulting from obstructive jaundice or from biliary fistula has been told so often that it needs no repetition here, but the group of cases in which there is inadequate absorptive surfaces of the intestine deserves some consideration. A deficiency of prothrombin as a cause of bleeding in cases of various intestinal disorders is something new in clinical medicine. Although instances of deficiency in prothrombin referable to the effect of intestinal disorders are not often encountered, they do comprise a rather distinct group and one which bears close observation. When patients who have extensive disease of the intestine, such as sprue, chronic ulcerative colitis, intestinal obstruction or ileitis, or who have had multiple short-circuiting operations on the intestinal tract experience hemorrhage either before or after surgical treatment, deficiency in prothrombin should be recognized and corrected before other forms of treatment are instituted. One of the most important points in handling these conditions is for the physician to follow the level of prothrombin in the blood closely before and after operation in all cases of abnormalities of intestinal mucosa, particularly in cases in which the postoperative condition requires continued aspiration of gas and secretions from the intestinal tract. This practice has solved the mystery of obscure intestinal bleeding which occurs frequently in such cases and definitely has reduced postoperative morbidity and mortality.

It has been well demonstrated clinically that primary hepatic disease, such as cirrhosis, atrophy or chronic hepatitis frequently is accompanied by deficiency of prothrombin. This deficiency of prothrombin is not the result of deficiency of vitamin K but apparently is the direct result of severe hepatic damage. Under these conditions the deficiency of prothrombin usually is not relieved by administration of vitamin K in any amount. It is well to recall that instances of severe hepatic damage occur in any disease in which the liver might be involved, and although this group of cases is somewhat small this possibility must be considered. It is true that frequently repeated doses of vitamin K are necessary in order to produce the desired effect, but when the usual therapeutic dose of vitamin K has been doubled or tripled without producing the desired effect it is fairly certain that, regardless of the amount of vitamin K administered, there will be no response to elevation of prothrombin in the circulating blood.

Regardless of the etiologic factors in the deficiency of prothrombin of man, treatment in most instances essentially is the same. In cases in which there is inadequate bile in the gastrointestinal tract natural vitamin K₁ or synthetic compounds exhibiting vitamin K activity which are given by mouth should be accompanied by administration of from 5 to 10 grams (0.3 to 0.65 Gm.) of bile salts. Synthetic compounds with vitamin K activity, now available on the market and given orally in doses of from 1 to 2 mg daily, usually constitute an adequate dose. There also is available on the market a water soluble compound, 4-amino-2-methyl-1-naphthol hydrochloride, which can be given effectively by mouth without bile salts. This compound and other synthetic compounds also are available commercially for intravenous and intramus-

cular administration. Their action is rapid.³ Daily doses of from 1 to 2 mg usually are sufficient parenterally. Most investigators interested in this subject suggest that prior to operation in any of these conditions, regardless of the concentration of prothrombin in the blood, vitamin K in some form should be given for from one to two days. After operation, the concentration of prothrombin in the blood should be followed carefully and vitamin K administered as necessary. In instances in which the level of prothrombin in the circulating blood is sharply decreased before operation, vitamin K should be administered routinely preoperatively and postoperatively for several days, and the concentration of prothrombin in the blood should be determined for at least eight to ten days thereafter.

Some workers⁴ recently have felt that the change effected in a particular level of prothrombin by administration of vitamin K may provide some index as to the nature of the disease being treated, with particular reference to intrahepatic and extrahepatic jaundice. Data now at hand do not unequivocally establish this fact.

Deficiency of Prothrombin Among Newborn Infants—It is agreed generally that during the first few days of an infant's life a deficiency of prothrombin exists in the circulating blood. The cause of this normal physiologic deficiency, however, is still controversial. Waddell and Guery were the first to report the important discovery that this physiologic deficiency of prothrombin of newborn infants and the bleeding tendency which sometimes developed could be corrected by administration of vitamin K. Since that time numerous reports have appeared concerning the effect of the various compounds possessing vitamin K activity on the level of prothrombin of newborn infants and the effect of such compounds on the hemorrhage which frequently occurs. The important suggestion also has been made that the deficiency of prothrombin existing at the time of birth might account in many instances for the intracranial hemorrhages which sometimes follow protracted labor and which frequently result in permanent paralysis.

It has been reported and well established by several groups of workers that administration of vitamin K to mothers prior to delivery will prevent the usual fall in the level of prothrombin in the blood which is observed among newborn infants and that administration of vitamin K to the newborn infant also will increase concentration of prothrombin in the plasma.⁵

On the basis of work now available, it appears that 2 mg of menadione given by mouth to a mother one half to forty-eight hours before delivery is effective in preventing hemorrhagic disease of the newborn infant.⁶ There is good evidence to indicate that, although the feeding of vitamin K to the infant after birth increases the concentration of prothrombin, the concentrations in these instances are not as high as those achieved by antepartum administration of the vitamin to the mother.

Many workers believe that instances of cerebral hemorrhage occurring in the course of birth with minimal trauma are precipitated by small hemorrhages which endure for a number of days. For this reason many workers interested in this problem believe that the lives of some of the infants might be saved if the blood at birth exhibits better properties of coagulation. Most investigators believe that vitamin K given in some form should be administered to every mother at the onset of labor. Some still insist that the vitamin should also be given to the newborn infant as an added precaution. In any event, the plan is so simple, the vitamin so cheap and the toxic reactions so minimal that this program should be adopted universally in the hope of preventing injury at birth.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ISOTONIC SOLUTION OF THREE CHLORIDES

(See New and Nonofficial Remedies 1942, p 427)

The following dosage form has been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH

Ringer's Solution 500 cc and 1000 cc Upjohn Infusion Bottles. Each hundred cubic centimeters contains 0.7 Gm of sodium chloride-U S P, 0.03 Gm of potassium chloride-N F and 0.025 Gm of calcium chloride-U S P.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1942, p 150)

The following dosage form has been accepted:

E S MILLER LABORATORIES, INC., LOS ANGELES

Tablets Sulfathiazole 0.5 Gm (77 grains)

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1942, p 555)

The following dosage forms have been accepted:

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Tablets Thiamine Hydrochloride 1 mg, 3 mg, 5 mg

Ampul Solution Thiamine Hydrochloride, 10 mg per

cc 1 cc Preserved with 0.5 per cent of chlorobutanol

Solution Thiamine Hydrochloride, 10 mg per cc 15 cc

vial Preserved with 0.5 per cent of chlorobutanol

Ampul Solution Thiamine Hydrochloride, 25 mg per

cc 1 cc Preserved with 0.5 per cent of chlorobutanol

Solution Thiamine Hydrochloride, 25 mg per cc 15 cc

vial Preserved with 0.5 per cent of chlorobutanol

Ampul Solution Thiamine Hydrochloride, 50 mg per

cc 1 cc Preserved with 0.5 per cent of chlorobutanol

Solution Thiamine Hydrochloride, 50 mg per cc 15 cc

and 50 cc vials Preserved with 0.5 per cent of chlorobutanol

Solution Thiamine Hydrochloride, 150 mg per cc

5 cc vial Preserved with 0.5 per cent of chlorobutanol

ANTIPROTHROMBIN THERAPY

Elsewhere in this issue appears a series of four papers on the development of dicoumarin as a substance definitely concerned with the mechanism of coagulation of the blood The record of the development of this product is one of the most dramatic stories in the field of chemotherapy In brief, the observation of a peculiar disease occurring in animals led to an investigation of the nature of its causation and then to an effort to apply the product producing the disease to a useful purpose in the control of the physiology of the human being

Cattlemen of the Middle West have long been familiar with the toxic effects of improperly cured hay or silage One type of hay intoxication was studied in detail about twenty years ago by Schofield¹ of Canada and Roderick² of North Dakota This syndrome was observed in cattle, sheep or rabbits fed on spoiled sweet clover (*Melilotus alba* or *Melilotus officinalis*) and was therefore named "sweet clover disease" The disease is characterized by an almost complete loss of the clotting power of the blood with resultant multiple hemorrhages in internal organs and tissue In its earlier stage the disease can be cured by eliminating spoiled sweet clover from the daily diet plus massive blood or serum transfusion from normal animals If not thus treated, however, the "hemorrhagic sweet clover disease" usually proves fatal

Roderick,³ Quick⁴ and others showed that the reduced clotting power of the blood is due to destruction or inactivation of prothrombin After a decade of repeated failures Roberts,⁵ Campbell⁶ and others succeeded in extracting the toxic agent from spoiled sweet clover From such extracts they obtained a crystalline material with the empirical formula $C_{19}H_{12}O_6$ (melting

point 288-289 C) This product was two hundred times more toxic than the original spoiled hay, from which they concluded that spoiled sweet clover contains approximately 0.03 mg per gram of the active toxic factor

Detailed chemical analyses with artificial synthesis of this toxic agent were subsequently made by Stahmann and his colleagues⁷ of the University of Wisconsin The Wisconsin chemists conclude that the substance is 3,3'-methylene-bis-(4-hydroxycoumarin) Tested on rabbits, their synthetic product and the natural toxin were of identical toxic and antiprothrombic titers Stimulated by an anticipated research interest in this anticoagulant, 3,3'-methylene-bis has been made commercially available by Swedish biochemists and offered under the nonproprietary name AP (antiprothrombin)

Lehmann⁸ found that in rabbits the lethal dose of this commercial product is 250 mg per kilogram of body weight Death is apparently due to kidney injury The substance, however, can be given by mouth in doses of 3 to 4 mg per kilogram of body weight without demonstrable toxic effects One 4 mg oral dose causes an 80 per cent fall in prothrombin index within twenty-four hours Daily repetition of this dose for twenty days causes a further lowering of the prothrombin titer to about 10 per cent of normal This prolonged daily administration also is without demonstrable deleterious effects Similar results were previously reported by Overman⁹ Lehmann further showed that the substance is apparently nonantigenic for rabbits, since they do not acquire demonstrable immunity to its subsequent administration

Encouraged by these experimental data, Lehmann began therapeutic tests on man The Swedish clinician found that when 0.25 to 1 Gm of AP is given by mouth a fall in prothrombin index occurs in man similar to that produced in lower animals This fall is usually without concomitant toxic effects In a few cases mild nausea or diarrhea was observed after the first dose but not after subsequent administrations Thus far 17 cases of thrombosis have been treated with this anticoagulant In each case the resulting fall in prothrombin titer was accompanied by clinical improvement, as shown by a fall in temperature and diminished turgor of the leg In all cases of phlegmasia alba dolens the course of the disease was shortened and increase in the thrombosis did not occur after the beginning of AP administration Oral administration of AP for the prevention of postoperative thrombosis is now under investigation

Whether or not administration of AP hastens the liquefaction or absorption of previously formed thrombi

or fibrin deposits has not yet been determined. Meanwhile American botanists have become interested in the sweet clover toxin. Brink¹⁰ and others, for example, are speculating on the possibility of finding or developing varieties of sweet clover relatively free from coumarin, the basic plant component from which the toxic agent is formed during spoilage.

HUMAN ALBUMIN IN MILITARY MEDICINE

Albumin makes up about 62 per cent of the total protein of human plasma and is chemically the most soluble and most stable of the plasma proteins. Its smaller molecular weight and greater net charge render it more important than globulin in maintaining the colloid osmotic pressure of the plasma. This pressure is the principal force counteracting filtration pressure, hence albumin plays a major part in maintaining the volume of fluid in the blood stream. Because of its molecular symmetry, albumin makes a less viscous solution than the other proteins and therefore can be readily injected in concentrations of 25 per cent. The advantage of plasma over solutions of salt and dextrose in the treatment of shock depends on the osmotic pressure exerted by its proteins (chiefly albumin), which keeps fluid in the circulation at a time when protein is being lost faster than it can be synthesized. Hence, in the emergency treatment of shock, albumin offers distinct practical advantages because it is stable, compact and ready for instant use.

Because the urgent demands of treatment in clinical cases of shock preclude detailed study, Heyl and Janeway¹ attempted to evaluate the physiologic effect of human albumin solutions in man under carefully controlled conditions of a blood volume depleted by venesection. The plasma volume was first determined in normal subjects. Immediately thereafter a rapid venesection of approximately 15 per cent of the blood volume was performed, the amount withdrawn being carefully measured. The injection of concentrated (25 per cent) albumin was begun at once. One hour later the plasma volume was again determined, and the trend of plasma volume was followed by frequent determinations of the values for hemoglobin, hematocrit reading and total protein. The results of these quantitative observations showed that concentrated human albumin will rapidly augment the plasma volume by drawing fluid into the circulation. Furthermore, calculations from these experimental data indicated that each gram of injected albumin (dose, 30 to 35 Gm) is capable of adding 14 to 24 cc of fluid to the plasma, with an average in 9 subjects of 18 cc at one hour after injection. This result, Heyl and Janeway say, confirms *in vitro* studies of osmotic pres-

sure which form the basis for the standard albumin unit of 25 Gm, which is therefore equivalent to about 450 cc of circulating plasma or 500 cc of citrated plasma.

Evidence that human albumin is safe and effective under clinical conditions is supplied by Woodruff and Gibson,² who report the effects noted in 200 instances in which albumin was given. Fifty-one were tests for reactions and eight were experiments, while the remainder were therapeutic injections in clinical cases. The albumin used in the study was prepared under the direction of Dr E J Cohn of the department of physical chemistry at Harvard Medical School by methods developed in the Harvard plasma fractionation laboratory. The types of cases treated were classified as shock due to trauma, hemorrhage, operation and infection, early and late burns, hypoproteinemia, experimental cases and miscellaneous conditions. The twenty-one preparations released for clinical use gave almost no reactions when tested in 48 cases. Among the 141 cases in which clinical treatment with albumin was given there were nine fairly definite reactions. Five of these were merely flushing or slight lumbar pain, while four were severe chills or fall in blood pressure. Albumin produced prompt recovery in most cases of surgical shock. Rapid and pronounced hemodilution was shown to occur. One unit of concentrated human albumin (100 cc 25 per cent solution) was used as the initial dose in shock, repeated in fifteen to thirty minutes if necessary. Further, these investigations showed that protein loss in burns can be replaced and the hemoconcentration prevented or corrected. In severe injuries and shock, transfusions of whole blood or intravenous saline solution enhance the effect. When intravenous fluids are given, they should contain at least 2 units of albumin per liter. The initial dose for burns is 1 or more units, depending on the extent of the burn. Subsequent doses should be regulated so as to prevent definite hemoconcentration and should be given in the ratio of 2 units of albumin per liter of solution.

The administration of human serum albumin may be considered an established procedure on the basis of this work and the work which has preceded it. The third paper of this series, by Newhouser and Lozner,³ describes the standard Army-Navy package of serum albumin human (concentrated). For this purpose a "unit" of human serum albumin is defined as 25 Gm. This is osmotically equivalent to approximately 500 cc of citrated plasma. In the standard package the 25 Gm is dissolved in 100 cc of buffered diluent, in which concentration it is stable for temperatures up to 50 C. The solution is contained in a double ended glass ampule, rubber stoppered at each end. Each ampule

together with the apparatus for its administration is enclosed in a metal can. Three of these cans, containing the osmotic equivalent of 1,500 cc. of citrated plasma, are packaged in a fiber board box.

Because of this and previous work, a new method of great effectiveness has been made available for combating shock, hemorrhage and burns. Furthermore, this series of investigations may be recognized as a demonstration of cooperative research at its best.

Current Comment

PREMEDICAL EDUCATION AND THE EIGHTEEN YEAR OLD DRAFTEE

In an address before the Congress on Medical Education and Licensure in 1939 President J. B. Conant of Harvard University called attention to the fact that the total professional training of medical men depended to some extent on their plans for the future. Those contemplating research as a career would require much more of the fundamental sciences than would those who are looking forward to general practice. The exigencies of war have already demonstrated the possibility of serious modifications of technics and practices which in times of peace seem unalterable. The acceleration of medical education and the proposed changes in licensure are examples. In 1939 President Conant made the following suggestions:

Encourage college freshmen who are looking forward to a medical career to apply for admission to a medical school three years in advance. Let the admission committee base its rejection or conditional acceptance of such applications on the school record, on the first year college record and on performance in such tests as the scholastic aptitude test. After the undergraduate in question has been tentatively enrolled as a future medical school student, let there be cooperation between the medical school and the college in working out through a joint committee an intelligent college program for the remaining three years.

This proposal by President Conant, it has been suggested, may be part of the answer to the maintenance of an adequate number of properly qualified young men in the field of premedical and medical education during the present emergency. The average age of young men at graduation from high school is 17.2 years. If they are enrolled in college before they are 18 years of age they might be deferred by selective service boards until they have completed the session in which they are enrolled. Under the plan proposed by President Conant of Harvard they could be matriculated in the medical school after the completion of the first year of premedical education and would thus be made immediately available for the reserve of the Army or Navy medical departments. Obviously young men who could not pass the physical examination for such reserves might have to be considered in some different manner. The proposal by President Conant is supplemented by his suggestion that the old concept of four years of scientific and liberal education, followed by four years of professional training, be replaced by a system in which the whole eight years is regarded as a unit to provide a balanced intellectual diet suited to each student's talents and interests.

A HEMOPHILIA-LIKE DISEASE IN SWINE

Animal maladies which are similar to those encountered clinically in man are of special interest because the probability of developing therapeutic measures a clinical condition is enhanced when a similar situation can be studied experimentally in animals. A hemophilia-like disease has been found in swine. The condition first attracted the attention of Hogan and his co-workers,¹ who noted that a number of hogs in the Missouri Agricultural Experiment Station herd possessed a defective blood clotting mechanism. Many of the animals have died from hemorrhage, either spontaneous or as the result of minor wounds. The bleeders are progeny of an inbreeding investigation, and the affected animals are closely related. Recently the characteristics of the disease were described², just as in clinical hemophilia, the bleeding time by Duke's method³ is normal. If an incision of any extent is made, however, the bleeding time is prolonged indefinitely. A 1 cm. slit in the edge of a defective swine's ear, for instance, may result in death. Examination of the blood of affected animals shows normal concentrations of prothrombin, calcium and fibrinogen. There is a deficiency of readily available thromboplastin, however, and the whole blood coagulation time is greatly extended. The platelets, though normal in number, are abnormally stable. The differential diagnosis of hemophilia from other hemorrhagic diseases has been carefully studied by Quick,⁴ who has outlined a diagnostic procedure which includes observations on the coagulation time of the blood and of recalcified oxalated plasma, as well as on clot retraction, bleeding time and prothrombin level. The application of Quick's method to bleeders and normal swine shows that the characteristics of the porcine disease fit closely the criteria set up for the diagnosis of hemophilia. Indeed, the disease does not differ in any significant way from human hemophilia, except that in swine the defect is not sex-linked. Both male and female swine are subject to the bleeding disease, and both sexes may transmit it.

SENATOR EUGENE D. MILLIKIN, COLORADO, SPEAKS FOR THE RECORD

On November 16 Senator Eugene D. Millikin of Colorado, a member of the subcommittee of the Senate Committee on Education and Labor, which is holding hearings on medical manpower, made the following statement for the record:

I would like to say if there is anything in the record that indicates any criticism on the part of this Committee of the physicians generally or of the American Medical Association, I should like to dissociate myself from that criticism. I repeat that a transcript should be furnished to the American Medical Association, so that they may reply to anything that they feel is critical of them.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

THE CRITICAL ANTIMALARIAL PROBLEM AND ITS SOLUTION

It is axiomatic that troops cannot operate successfully in endemic malarial areas without an effective antimalarial drug. Malaria is present throughout most of the tropical and subtropical world. The extent of operations in these regions is steadily increasing and it is conceivable that they may grow to tremendous proportions within a short time.

Ninety per cent of the world's customary sources of quinine was cut off when the Japanese invaded Java and the Philippines. India has in the past frequently imported cinchona bark from Java to bolster her supply. South America has for many years been importing bark from Java for domestic use.

What measures should be taken to safeguard our limited stocks? Early in May the War Production Board recognized the critical nature of the problem. In order to avail itself of medical advice it asked the National Research Council to form a committee on drugs and medical supplies to investigate and advise not only on the many problems which the quinine scarcity presented but also on any other matters pertaining to drugs and medical supplies which concerned the War Production Board. This committee has two subcommittees, one on essential drugs, the other on hospital and surgical supplies. The committee has also used the advice of other National Research Council committees, such as the Subcommittee on Tropical Diseases, for answers to specific problems in the therapy of malaria, and the Committee on Surgery for technical problems related to surgical supplies.

The program worked out by the joint efforts of the War Production Board and the National Research Council progressed as follows:

1 The War Production Board issued "Quinine Order M-131," which froze present stocks and restricted the use of quinine and other cinchona alkaloids to the treatment of malaria, except that quinidine could also be used for the treatment of cardiac disorders. Requests for quinine for the treatment of various other conditions, including quinine urethane and quinine urea as local anesthetics, quinine in sodium morrhuate for varicose vein injections, quinine salts for induction of labor, quinine salts in the treatment of night cramps, multiple sclerosis, amyotrophic lateral sclerosis, myotonia atrophica, paralysis agitans and myotonia congenita, have all been carefully considered and denied with the exception of the use of quinine in the treatment of myotonia congenita.

2 Repeated persuasive efforts in the trade press have been instituted by the War Production Board to bring in all unopened packages of quinine, and now the machinery is being set up for bringing in opened packages, analyzing each and pooling according to the type of preparation.

3 To effect the maximum antimalarial value of available cinchona bark from South America, the National Research Council undertook to investigate the feasibility of substituting totaquine for quinine in the treatment of malaria. Totaquine had been recognized previously by the U. S. Pharmacopeia and a standard set which appears in the twelfth edition. This standard seemed to allow for too much latitude both in quinine content and in total crystallizable alkaloid content. Accordingly, the National Research Council asked the U. S. Pharmacopeia to revise the monograph to obtain a more uniform

standard. As the result the U. S. Pharmacopeia adopted the following monograph, which will appear in a supplement of the twelfth edition:

'Totaquine is a mixture of alkaloids from the bark of *Cinchona succirubra* Pavon and other suitable species of *Cinchona*. It contains not less than 7 per cent and not more than 12 per cent of anhydrous quinine, and a total of not less than 70 per cent and not more than 80 per cent of the anhydrous crystallizable cinchona alkaloids the designation 'crystallizable alkaloids' referring to cinchonidine, cinchonine, quinidine and quinine.

'Totaquine of a higher quinine percentage may be reduced to the official quinine standard by a mixture with totaquine of a lower percentage or with any of the diluents permitted for powdered extracts under Extracta page 174, provided the total anhydrous crystallizable cinchona alkaloids do not fall below the required percentage.

The U. S. Pharmacopeia on the advice of the National Research Council recommended the dose to be 10 grains three times a day for seven days."

It was the considered opinion of the Subcommittee on Tropical Diseases and the Committee on Medicine of the National Research Council that in this dosage totaquine should prove to be as effective as quinine sulfate in the oral treatment of malaria. A satisfactory price structure has been set up for cinchona bark from South America by the Board of Economic Warfare, and every effort is being made to stimulate importation.

4 The production of atabrine has been stimulated by the War Production Board, and the present outlook on production sufficient to supply all anticipated needs is practically assured. Extensive chemical, pharmacologic and clinical investigations have been conducted by various groups of the National Research Council working under grants by the Office of Scientific Research and Development. The chemical studies have adequately demonstrated the chemical purity of the atabrine produced in this country. Pharmacologic and clinical investigations have revealed temporary gastrointestinal disturbances in a variable percentage of persons receiving atabrine in the suppressive (prophylactic) treatment of malaria. Further study is under way to elucidate the cause and remove if possible these disturbances. There is a tendency to the development of a yellow pigmentation of the skin during administration which disappears after the drug is stopped. This is harmless and not associated with any disturbance in liver function.

5 Experience with the use of atabrine by the British both therapeutically and as a suppressive indicates that it is an effective antimalarial and in some ways superior to quinine. It is slower in action and therefore not as useful in the initial treatment of malaria but after one to three days of quinine therapy atabrine is exceedingly effective. At a recent meeting of the Subcommittee on Tropical Diseases of the National Research Council the following program of dosage was endorsed as an efficient routine of therapy:

- (1) *Combined QAP Treatment* (method of choice)
 - (a) Totaquine or Quinine sulfate 0.64 Gm (10 grains) three times daily after meals for two or three days or until pyrexia is controlled. Then give
 - (b) Atabrine 0.1 Gm (1½ grains) three times daily after meals for five days. Then after two days without antimalarial medication give
 - (c) Plasmodochin 0.01 Gm (⅓ grain) three times daily after meals for five days, except for the debilitated patient, who should receive only two doses daily. (Discontinue if toxic symptoms occur. Never give atabrine and plasmodochin concurrently.)

(2) *Atabrine Plasmachin Treatment* (may be used for simple vivax infections and in other infections when no totaquine or quinine is available)

(a) Atabrine, as above for seven days. Then, after two days without antimalarial medication give plasmochin 0.01 Gm three times daily for five days, as above

(3) *Totaquine or Quinine-Plasmachin Treatment* (method when no atabrine is available)

(a) Totaquine or quinine sulfate, as above, for seven days, during the last five of which accompany each dose of totaquine or quinine with plasmochin 0.01 Gm three times daily

(4) *Suppressive Treatment*

(a) Atabrine. Give 0.1 Gm (1½ grains) twice daily after meals on two days a week, allowing a two or three days interval between days of medication

It was the consensus of this subcommittee that until we have had more experience with the use of atabrine it should be used only under the guidance of a physician or public health officer

6 Government stockpiles have been recommended not only for quinine but for the other alkaloids (cinchonine, cinchonidine

and quimidine) and totaquine, and the Defense Supplies Corporation is purchasing against these stockpile recommendations

It is anticipated on the basis of recent investigations by the Board of Economic Warfare that the barks from South America of low quinine content but sufficiently rich in total crystallizable alkaloids (quinine, quimidine, cinchonine, cinchonidine) to make totaquine of U S P standards will be found in sufficient quantity to enable totaquine to replace civilian quinine requirements. The amount of this bark which is available has been an unknown factor, because its low quinine content has not made it previously marketable

If every physician in civilian practice and every public health officer will follow the recommendations of the Subcommittee on Tropical Diseases regarding the use of atabrine and will use totaquine in place of quinine whenever totaquine is available, an important and material conservation in our limited stocks of quinine will be accomplished

LEWIS H. WEED, M.D.

Chairman, Division of Medical Sciences, National Research Council

ARMY

CHEMICAL WARFARE SCHOOL

A training school for physicians in western Pennsylvania in the medical aspects of chemical warfare was opened at the Mellon Institute, Pittsburgh, November 2, to be held on four consecutive Mondays. The program was carried out under the auspices of the Allegheny County Council of Civilian Defense and the committee on postgraduate education of the Allegheny County Medical Society. T. K. T. Kruse, Ph.D., Pittsburgh, lectured, November 2, on "Pharmacology of Chemical Warfare Agents: Collective Decontamination." Dr. Irwin M. Pochapin, Pittsburgh, spoke, November 9, on "Scope and Purpose of Chemical Warfare: Classification of Chemical Warfare Agents." Dr. Pochapin also spoke, November 16, on "Treatment of Chemical Agent Casualties: Individual Protection of Technical Personnel and of the Civilian Population." On November 23 he will speak on "Treatment of Chemical Warfare Casualties: Demonstrations, Essential Supplies for First Aid."

COMMISSION TO STUDY TYPHUS IN WAR ZONES

The War Department and the Navy Department on November 19 announced organization of the United States of America Typhus Commission, composed of four typhus research specialists under the direction of Rear Admiral Charles S. Stephenson, Medical Corps, U. S. Navy. The commission will aid in the prevention and control of typhus among the military forces of the United Nations and civilians in war areas throughout the world. Other members of the commission are Lieut. Col. Harry Plotz, Medical Corps, Army of the United States, Senior Surgeon Adolph Rumreich, U. S. Public Health Service, and Major John C. Snyder, Medical Corps, Army of the United States.

Admiral Stephenson is a veteran with twenty-nine years' service in the Navy Medical Corps. He is director of the Division of Preventive Medicine, Bureau of Medicine and Surgery, Navy Department, and his nomination for the grade of rear admiral was recently confirmed by the Senate. He will serve in that grade until the work of the Typhus Commission is completed.

The entire commission will be militarized so that its members will be able to enter theaters of war operations throughout the world.

The commission will function as a board of strategy against typhus and will coordinate the efforts of the military, the government and the civilian in the fight against typhus. The primary purpose of the commission will be to develop informa-

tion on which to base specific recommendations for the protection of our armed forces. Information so obtained will have a direct bearing on the protection of the civilian population of the United States against the introduction of typhus fever.

More than two years ago there was developed in the Office of the Surgeon General of the Army an organization known as the Division of Medical Intelligence. This organization, headed by Lieut. Col. Thomas Whayne, collects information concerning the prevalence of disease in foreign countries. The data thus collected concerning typhus show that in parts of the world a steady increase in the incidence of typhus within the last year has occurred.

Operating in areas where typhus is endemic, the commission will investigate factors which cause the spread of the disease. Liaison will be established between the commission and the government and military organizations of countries in which the commission will operate.

Heretofore the main reliance in the control of typhus has been on delousing the population. United States troops which enter endemic typhus areas are equipped with delousing equipment but the method is cumbersome. At present three vaccines are available in the United States which give a high degree of protection to animals. These vaccines have not been proved on human populations because the United States has no typhus in an epidemic form. One of these vaccines is made from infected lice, another from the lungs of infected mice and rats, and the other from the infected yolk sacs of developing chick eggs. Insecticides have been developed which have been effective in laboratory experiments and only need to be given field trials. Research has been done in the field of insect repellents, however, there is a need to try these repellents and disinfectants under natural rather than under artificial conditions.

Admiral Stephenson said the job of this commission is vital for typhus can wreck any military operation, no matter how well planned.

Colonel Plotz said the army has a special laboratory where methods of preparing typhus vaccines are being actively studied and important progress has been made. His laboratory in the Pasteur Institute in Paris, where he was engaged in typhus research from 1921 until 1939, is in the hands of the Germans. Colonel Plotz was born in New Jersey and received his M.D. degree from the College of Physicians and Surgeons, Columbia University, New York. In 1914 he was invited by the government of Serbia to study a typhus epidemic there. In 1919 and 1920 he was in Poland investigating typhus. In 1921 he entered the Pasteur Institute in Paris, where he remained until 1939. He has been in the Army of the United States since 1940.

Dr Rimmreich was born in North Dakota. He received his M.D. degree in 1920 from the Washington University School of Medicine, St. Louis, and was commissioned in the Regular Corps of the Public Health Service in 1924. While on duty in the National Institute of Health, he conducted investigations of typhus fever and Rocky Mountain spotted fever. In 1935 Dr Rimmreich was assigned to the United States embassy in Moscow. He investigated typhus fever in Russia.

Major John Crayton Snyder was born in Salt Lake City and graduated from the Harvard Medical School. He became a staff member of the International Health Division, Rockefeller Foundation, and in 1941 went to Spain to study a typhus epidemic there. Major Snyder is a consultant to the Secretary of War on epidemic diseases and a member of the Commission on Tropical Diseases of the Board for Investigation and Control of Influenza and Other Epidemic Diseases in the Army.

GREENBRIER HOTEL CONVERTED INTO ARMY HOSPITAL

The Greenbrier Hotel and all facilities and grounds owned by the White Sulphur Springs, Inc., at White Sulphur Springs, W. Va., was acquired by the War Department on September 29 for conversion into a 2,000 bed army general hospital. The hospital will be named general hospital, but the name has not been chosen to date.

Col Clyde M. Beck, M. C., U. S. Army, has assumed his post as commanding officer and Lieut. Col. Sam F. Seely, M. C., U. S. Army, has been named as executive officer. No other medical corps officers have reported for duty to date, although several administrative group officers are now on duty.

Colonel Beck was transferred from Camp Joseph T. Robinson, Arkansas, where he served as commanding officer of the station hospital for nearly two years. Colonel Seely was transferred from Washington, D. C., where as executive officer of the Procurement and Assignment Office he had been on duty for the past year.

PUEBLO'S HOSPITAL UNIT ACTIVATED

The 64th Surgical Hospital Unit, sponsored by St. Mary's Hospital, Pueblo, Colo., was recently activated at Fort Ord, California, and later went on extended maneuvers. The medical officers of the unit had been called to active duty during the early part of 1942 but later were assembled and activated as a unit. The director of the unit is Major Paul M. Ireland, other medical officers serving with the unit at the time of the report in the November issue of the *Rocky Mountain Medical Journal* are Lieut. James S. Norman, Major Paul M. Ireland, Major Albert M. Tipple, Major Merrill W. Michels, Major Robert Sterling, Major Edwin W. Varley Jr., Capt. Hiram E. Armstrong, Capt. Francis S. Adams, Capt. Arnold S. Niemeyer, Capt. John Mihalick, Colorado Springs, Capt. Harold J. Beck, Capt. George C. Christie, Canon City, Capt. Eugene F. Pfile, Trinidad, Capt. Ward C. Fenton, Rocky Ford, Capt. Richard

H. McIlroy, Capt. Irvin I. Schatz, Capt. Alton S. Hansen, Lt. Junto, 1st Lieut. William N. Baker, 1st Lieut. Raymond A. Nethery, 1st Lieut. Carl W. Swartz, 1st Lieut. Roy A. L. Swanson, 1st Lieut. Walter S. Johnston. All of these officers are from Pueblo, except those whose home address is indicated.

THE SURGEON GENERAL'S OFFICE

The Surgeon General of the Army, Major Gen. James C. Magee, in an address before the Association of Military Surgeons at San Antonio, Texas, in November, is reported to have said that newly developed mobile pack equipment for the transportation of supplies for a battalion aid station is now being tested and if approved it will free medical personnel from restrictions imposed by the use of wheeled vehicles which the present load of equipment necessitates. General Magee also told of the development of an operating unit for use with armored forces in the field which consists of a van type bus of the six wheel variety which can be quickly moved and is always ready to begin operations immediately on arrival at the desired place.

The War Department has announced the appointment of Mr. Edward Reynolds, New York, as special assistant to the Surgeon General to have supervision of the nonprofessional functions of the Surgeon General's Office relating primarily to the procurement of medical supplies. Mr. Reynolds graduated from Harvard University in 1915, served as an officer in the Navy in the first world war and has been president of the Columbia Gas and Electric Corporation.

CLASS OF AVIATION PHYSIOLOGISTS

Another class of aviation physiologists was graduated at the School of Aviation Medicine, Randolph Field, Texas, October 24. The certificates of graduation were presented by Lieut. Col. Victor A. Byrnes, M. C., U. S. Army. The course in aviation physiology covers the effects of lowered barometric pressure on personnel, the operation of low pressure chambers, the effect of flight on man, the theory and practical use of oxygen equipment and the conduct of high altitude indoctrination and classification. The graduates comprised both officers and enlisted men of the medical corps and aviation corps, among the former were 1st Lieuts. Richard Bentley Baker, George J. Pastorius, Clark K. Sleeth and Charles Bruce Taylor.

SHORTEN COURSE FOR ARMY DIETITIANS

The War Department announced in November that more than two hundred dietitians will be trained each year for service at army hospitals at home and abroad. The course of training will comprise a six month pretraining course at civilian hospitals and a six month course at army hospitals. The first group of dietitians was expected to proceed to army hospitals on December 1.

CIVILIAN DEFENSE

LESSONS FROM BRITISH EXPERIENCE IN CIVILIAN DEFENSE

GEORGE BAEHR, M.D.
Office of Civilian Defense

Three years of British experience with air raids have significantly modified earlier concepts regarding the field casualty services. The following observations made on a recent inspection of emergency medical facilities in England and Scotland are forwarded for the information of regional medical officers and for transmission through state chiefs to local chiefs of emergency medical services.

1 Heavy raids occur invariably at night, heavier high explosive bombs and land mines are now being employed up to 2,000 Kg., with much greater destructive effects. Incendiary bombs are used in much larger numbers and fire is now the most serious hazard. Daylight raids are usually hit and run affairs in which solitary planes participate.

2 In large cities the field casualty services may handle 2,500 to 3,500 casualties during a night raid. All serious casualties are moved directly to hospitals, never to first aid posts. Heavy raids are apt to be repeated on subsequent nights when the protective forces are exhausted.

3 A large fleet of four stretcher ambulances is essential for life saving. Fourteen thousand ambulances were made in England and Scotland by purchasing used cars, stripping them and then mounting a simple ambulance body on the chassis. London uses over fifteen hundred of such ambulances and five hundred and fifty sitting case cars. The use of tradesmen's trucks proved universally unsatisfactory, three out of four never arrived on the scene and lives were lost as the result of the delay and confusion. Because of the large number of casualties to be transported in a few hours, no ambulances which carry less than four stretchers are employed. For the simultaneous evacuation of damaged hospitals, a fleet of two hundred converted busses carrying 10 stretcher cases and 6 to 10 sitting cases are immediately available and another two hundred are obtainable within two hours.

4 Casualty stations (British fixed first aid posts) are necessary at or near all hospitals and at places more than a mile from hospitals to care for minor casualties which do not require hospitalization. Many are now on a care and maintenance basis and are activated only during a raid. When functioning, the staff usually consists of one or two doctors, several nurses and a variable number of aides and auxiliaries.

5 In large cities casualty stations need not be more numerous than one to 25,000 inhabitants, they should be located about a mile apart. There are less than three hundred in the London area with a population of about 10,000,000 and a land area more than twice that of greater New York. In smaller, thinly settled communities, they are more numerous in relation to population but the distances between them are proportionately greater than in metropolitan cities. Many of the minor casualties are moved to first aid posts in sitting case cars, some walk.

6 First aid parties (our stretcher teams) are not necessary, are a waste of manpower and are rapidly being eliminated. First aid at incidents is essentially a function of the rescue parties (our rescue teams), which extricate the casualties from under the debris of demolished buildings. All first aid parties in England and Scotland are therefore being merged into the rescue parties. They include a leader, an assistant leader and eight other members and are entirely independent of the fire department. They are a life saving service related to the medical services concerned in field casualty work.

7 The experiences of Britain under air raid conditions have dispelled many preconceived notions concerning first aid. Almost all raids occur at night, the victims are crushed under the debris of demolished buildings and are either dead or severely injured, less than a third are slightly injured and can be cared for at casualty stations, all the severely injured must go directly to a hospital, victims are invariably covered with dust and dirt, which hangs in the air for hours. The conditions under which the rescue workers encounter the injured beneath the structural debris, the darkness and the dust which always fills the air, the large proportion of dead and severely injured, and the urgent need for immediate hospitalization make it impossible to apply most peacetime concepts of first aid.

8 Wounds are usually grossly contaminated and need only be covered with a shell dressing until the casualty reaches the hospital. Hemorrhage is usually controllable with a pressure dressing. The tourniquet is rarely employed. Burns are covered only with sterile gauze until the casualty arrives at the hospital. Tannic acid jelly as a first aid dressing for burns has been discarded because of the dirt which invariably contaminates the burned surface, because the jelly deteriorates rapidly and, lastly, because tannic acid ignites in the presence of phosphorus when applied to burns caused by the explosion of phosphorus-oil bombs.

9 Traction splints are not used. An exception is made if the casualty must be transported a long distance over country roads. Unlike army field experience in the last war, the few miles of travel to a hospital over the paved roads of a city do not warrant the application of traction, especially as the darkness and the conditions of an air raid also make hurried application of the procedure difficult or impossible. All that can be done is to place the fractured extremity gently in alignment, bind it with triangle bandages to the uninjured leg or to an improvised splint, or apply a Thomas splint if one is at hand. Movement of the fragments can also be minimized by snug application of the blankets according to the Wanstead technique of blanketing and by the use of sand bags, which should always be carried in the ambulance.

10 Shock is treated at the incident by prompt administration of adequate doses of morphine (up to $\frac{1}{2}$ gram for adults), nikethamide, proper blanketing, administration of fluids and the use of hot water bottles during transportation to the hospital. The use of plasma or blood transfusion is deferred until arrival at the hospital, it is ordinarily quite impossible in the darkness, dirt and confusion at the incident.

11 The presence of a physician at the incident is invaluable but more than one is unnecessary. In fact, one physician may cover several nearby incidents, leaving his nurse or one of the nursing auxiliaries of his emergency team at the incident while he moves temporarily from one to another in the immediate neighborhood.

12 Even though a single night's casualties requiring hospitalization may total 1 or 2 thousand, large hospitals rarely receive more than 50 to 100, the load being distributed as evenly as possible throughout the city.

13 A large casualty receiving hospital is often related to one or more peripheral hospitals in the suburbs or in a country district. There are now four base hospital beds for each casualty bed in the cities.

14 On receipt at a local report and control center of a message from an air raid warden that an incident and casualties have occurred, an "express party" is immediately dispatched to the scene. An "express party" includes one rescue first aid party, one ambulance, one sitting case car and one mobile medical unit (our mobile medical team). The latter consists of one physician, one nurse and two auxiliaries. No other equipment and personnel of the emergency medical service is dispatched unless additional assistance is requested by the incident officer (usually a higher police official) or by the incident physician on the scene. In this manner useless movement is avoided and equipment and personnel of the community are carefully conserved.

ORGANIZATION SECTION

OFFICIAL NOTES

ARMY AND NAVY PHYSICIANS LISTED IN THE DIRECTORY AT WASHINGTON

For military reasons medical officers of the regular U S Army and the U S Navy on active duty, were listed in the new Seventeenth Edition of the American Medical Directory at Washington D C, with biographic data, titles, and local addresses as U S Army and U S Navy.

Officers of the Medical Reserve Corps, the Naval Reserve and the National Guard who are on extended active duty are listed at their home addresses followed by a symbol indicating their respective branch of service.

Reserve officers for whom home addresses could not be obtained are also listed at Washington, D C, without local addresses.

Users of the American Medical Directory are requested not to send mail to officers listed at Washington D C when only the address of the U S Army or the U S Navy is shown.

DOCTORS AT WAR

Owing to schedule conflicts, Doctors at War, which goes on the National Broadcasting Company network Saturdays at 5 p m eastern time, beginning December 26, cannot be broadcast in Chicago at that time. The program, therefore, will be heard in Chicago on a rebroadcast from 8 to 8 30 p m central time, over station WMAQ. Similar program conflicts may materialize in other communities. If the program is not heard at the regular time, local newspaper radio announcements should be consulted.

Persons who are interested in assuring local broadcasts of the program might profitably call the action of WMAQ in this regard to the attention of their local radio program department. It should be noted that the Blue Network, which is no longer the property of the National Broadcasting Company, cannot procure Doctors at War.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—H R 7633 has passed the House, providing for an increase in pay and allowances for members of the Army Nurse Corps and providing for the inclusion in the Medical Department of the Army of such female dietetic and physical therapy personnel as the Secretary of War may consider necessary. As passed by the House, this bill provides that the superintendent of the Army Nurse Corps will have the relative rank of colonel, assistant superintendents or directors will have the relative rank of lieutenant colonel or major respectively, the director of dietitians and the director of physical therapy aides will each have the relative rank of major, and all other assistant superintendents and assistant directors, chief dietitians and chief physical therapy aides will have the relative rank of captain. Chief nurses, head dietitians and

head physical therapy aides will have the relative rank of first lieutenant and head nurses, nurses, dietitians and physical therapy aides will have the relative rank of second lieutenant. Employment by the military establishment of female dietetic and female physical therapy personnel will hereafter be limited to persons appointed under the provisions of this bill, and appointments of such personnel under the provisions of any other law will be terminated as of the last day of the third month following the month in which the bill is enacted. The provisions of this bill relating to the Army Nurse Corps and to female dietetic and female physical therapy personnel will remain in effect during the present war and until six months thereafter. S 2769 has been reported to the Senate authorizing the rank of rear admiral in the Dental Corps of the United States Navy.

WOMAN'S AUXILIARY

Iowa

Members of the Polk County auxiliary have served as hostesses at the USO in Des Moines on the first and the third Wednesday of each month. Ten members furnish the refreshments and four serve them.

Oklahoma

As early as 1917 there was an auxiliary organized in Shawnee, and Oklahoma has had a state organization since 1928. At present there are ten counties organized in the state, with a total membership of 360. One of the primary goals for the state auxiliary this year is to form auxiliaries in the unorganized counties.

The Cleveland County auxiliary has sponsored a Red Cross course in home nursing, which has been taught by one of their members. The entire auxiliary is active in Red Cross work.

Wisconsin

The woman's auxiliary to the Washington-Ozaukee County Medical Society met on September 10 at the Ozaukee Country Club. Guests included Mrs Robert Radtke, Watertown, Mrs J Eichman, Allenton, Mrs W T Becker and Mrs V A Waldren, Cedarburg, and Miss Elizabeth Cathaus, Thiensville. News from the twentieth anniversary meeting of the national auxiliary at Atlantic City in June, as reported in the *Bulletin*, was reviewed by Mrs A H Barr, Port Washington. The

October meeting of the auxiliary was held in Port Washington. Following a 1 o'clock luncheon, the business meeting was held at the home of Mrs C C Stem.

The auxiliary to the Waukesha County Medical Society met at the home of its president, Mrs T H Nammacher, Oconomowoc, on October 7. Members heard the annual reports of the committee chairmen and were particularly interested in the scrapbook compiled by Mrs W T Murphy, Waukesha, archives chairman.

Dr P E Pifer, president of the Kenosha County Medical Society spoke to the woman's auxiliary on 'Excerpts of Legendary Medicine' at the home of Mrs C F Ulrich on October 6. At the business meeting, the members decided to work on surgical dressings for the Red Cross each Thursday afternoon. Mrs Alexander Schlapik announced that the group would send meat or fowl to the canteen each month.

The Woman's Auxiliary to the Medical Society of Milwaukee County met on October 9 at the Pfister Hotel. Forty members greeted the incoming president, Mrs H O Zurheide. The Reverend Lee J Ferry spoke on 'Associated Charities' and Mr Richard Rice discussed 'Civilian Defense'. Members enjoyed violin solos by Mrs Benjamin Lieberman and dramatic readings by Miss Inez Shabart. At a board meeting approval was voted to further the educational campaign of the Women's Field Army for the Control of Cancer.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Faculty Changes at Stanford—Dr Harold Phillips Hill, clinical professor of medicine, San Francisco, Stanford University School of Medicine, San Francisco, has been made professor emeritus. Full professorships have been granted to Dr Victor E Hall in physiology, John Field II, PhD in physiology, and Dr Charles E Smith in public health and preventive medicine.

Society News—The San Francisco County Medical Society devoted its meeting October 13 to a consideration of practical aspects of the problems of resuscitation. The speakers were Drs Hubert R Hathaway, William B Neff, John A Stiles and Leon Goldman, all of San Francisco.—Dr Paul C Bucy, Chicago, discussed 'Motor Cortex and Its Relation to Atetosis and Tremor' before the Hollywood Academy of Medicine October 8.

Dr Addis Awarded Cullen Prize—Dr Thomas Addis, since 1919 professor of medicine at Stanford University School of Medicine, San Francisco, has been awarded the Cullen Prize by the Royal College of Physicians in Edinburgh for 'the greatest benefit done to practical medicine in the last four years.' Dr Addis, whose research has included extensive study on the kidney, is a native of Edinburgh and a member of the Royal College of Physicians.

Grants for Tropical Disease Studies—The Josiah Macy Jr Foundation, New York, recently gave \$4,000 to Stanford University to aid studies in tropical diseases. Other recent grants for the same research include \$850 from the Carnegie Corporation of New York, \$400 from the National Academy of Sciences and \$200 from the May Esther Bedford Fund Inc., of Connecticut. Other subscribers to this cooperative project at Stanford are the Higher Studies Fund at Oxford, the British Association for the Advancement of Science, the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation, New York, and the Viking Fund, Inc., New York. Edward P Mumford, MSc, research associate, biology, is directing the project, which is an investigation of the geographic distribution of insects and other disease carriers and of the parasites of man in relation to the war and its aftermath. According to an announcement from Stanford University, the study is being made with special emphasis on the Pacific Islands with which Mr Mumford has been concerned in his research at Stanford since 1939.

COLORADO

State Medical Election—Dr George P Lingenfelter, Denver, was recently chosen president-elect of the Colorado State Medical Society and Dr Ralph S Johnston, La Junta, was inducted into the presidency. Dr Edward R Murgage, Denver, was named vice president and Dr John S Bouslog, Denver, was reelected constitutional secretary. Mr Harvey T Sethman, Denver, is the executive secretary.

New Editor of State Journal—Dr Lyman W Mason, Denver, assistant professor of obstetrics and gynecology, University of Colorado School of Medicine, has recently been made acting scientific editor of the *Rocky Mountain Medical Journal*. Dr Douglas W Macomber, Denver, was granted a leave of absence from the position to become a major in the medical corps of the Army of the United States.

ILLINOIS

Society News—Dr Herbert E Landes, Chicago, discussed hematuria before the McLean County Medical Society at Bloomington, November 17.—Dr Alfred D Biggs, Chicago, addressed the Kankakee County Medical Society, November 10, on problems of the newborn.

Chicago

Dr Landau Named Director of X-Ray Department—Dr George M Landau, director of the x-ray department of the Cook County Infirmary, Oak Forest, Ill., has been appointed director of the x-ray department of Cook County Hospital, filling the vacancy caused by the death of Dr Maximilian Hubeny last July. Dr Landau graduated at the University of Illinois College of Medicine in 1915.

The William T Belfield Lecture—Dr Andrew C Ivy, recently appointed chief scientific director of the U S Naval Medical Research Institute, Bethesda, Md., and Nathan Smith Davis professor of physiology and pharmacology, Northwestern University Medical School, gave the fourteenth annual William T Belfield Memorial Lecture before the Chicago Urological Society, November 19, on "The Physiology of the Urinary Bladder, with Special Reference to Its Nerve Supply."

University Blood Bank—A blood and plasma bank for the treatment of civilian patients is now in operation at the University of Illinois College of Medicine to serve the Research and Educational Hospitals and allied institutes in Chicago. Dr Milan V Novak, associate professor of bacteriology and public health at the medical school, is in charge of the blood and plasma library. The project is not connected with the blood bank program of the American Red Cross but is intended to help the hospitals, it was stated.

Fellowships in Industrial Surgery—Dr William A Larmon and John W Henderson have been awarded the first two of the James S Kemper fellowships in industrial surgery at Northwestern University. The amount of \$5,000 was awarded by Mr James S Kemper to subsidize fellows at the medical school to be trained in general surgery with special emphasis on industrial phases. The recipients will receive their training in the various hospitals affiliated with the university and the dispensary and the laboratories in the Montgomery Ward Building.

Drs Hektoen and Herrick Honored—Dr Ludvig Hektoen and Dr James B Herrick will be honored at the twenty-seventh annual dinner of the Institute of Medicine of Chicago in the Grand Ballroom of the Palmer House on December 2, in recognition of their many years of service to the institute. Dr Wilber E Post will preside at the dinner and speakers will be Dr James P Simonds, professor of pathology at Northwestern University Medical School, on "Ludvig Hektoen A Study in Changing Scientific Interests" and Mr J Christian Bay, librarian, John Crerar Library, 'James B Herrick Youth in Man Makes History.' Dr Hektoen and Dr Herrick are two of the founders of the Institute of Medicine and have been active on the board of governors since 1915, when the institute was founded. Dr Herrick was president in 1925 and Dr Hektoen in 1929. Dr Hektoen was also chairman of the board of governors from 1921 to 1940, when he became honorary chairman.

The De Lee Memorial Fund—More than \$50,000 to establish the Joseph B De Lee Memorial Fund was presented to the University of Chicago November 23 at a meeting honoring the late Dr De Lee, founder of the Chicago Lying-in Hospital. The fund will be used to provide fellowships in the Chicago Lying-in Hospital for young physicians engaged in the specialized study of obstetrics. Dr Morris Fishbein, Editor of *THE JOURNAL*, and Robert M Hutchins, LL.D., president of the University of Chicago, were the principal speakers at the meeting. Dr Fishbein's subject was "Maternal Care in the Post-War Period." The presentation of the fund was made by Dr M Edward Davis, professor of obstetrics and gynecology at the university's school of medicine and obstetrician and gynecologist at the hospital. Ultimately the fund will be increased to \$100,000. The largest single contribution of \$20,000 was a gift from the Mothers' Aid of the hospital. The present hospital is the outgrowth of a one man dispensary started by Dr De Lee. In 1917 it was housed in its first modern building. The present building was completed in 1931, and in 1938 the hospital was merged with the University Clinics. Dr De Lee was head of the hospital from its beginning until his retirement in 1939. He died April 2 of this year.

KENTUCKY

Society News—The Jefferson County Medical Society was addressed November 16 by Drs Wilfrid C Gettelfinger on "Cirrhosis of the Liver" and Charles H Maguire, "Pyloric Stenosis." Drs William Austin Bloch and Maurice G Buckles presented a case report on "Carcinoma of the Lung." All are of Louisville.—Dr William Barnett Owen, Louisville, discussed the Kenny treatment of poliomyelitis before the Louisville Medico-Chirurgical Society November 13.

Industrial Health Program—As a result of a meeting in Louisville, October 9, fifty new committees have been appointed to organize subcommittees on industrial health and welfare in the state. More than a hundred representatives of labor and management attended the meeting, at which the medical, engineering, safety and welfare offices of a good industrial hygiene program were discussed by prominent industrial hygiene and

safety experts. Reporting of occupational diseases is now required by law in Kentucky, thirty-four of which are included in a list of diseases "declared dangerous to the public health." The list is being sent to all physicians in the state.

MARYLAND

Society News—The Baltimore City Medical Society was addressed November 6 by Drs Philip B. Price on "Zinc Antiploresis in Treatment of Carcinomas", Edward M. Himmelfarb Jr. on "The Treatment of Advanced Carcinoma of the Scalp and Skull" and Leo Bridg, "The Treatment of Leukorrhea Due to Trichomonas Vaginitis", all are from Baltimore.

MASSACHUSETTS

Worcester Medical Library Moves—The Worcester Medical Library of the Worcester District Medical Society has been moved from its headquarters at 34 Elm Street to 57 Cedar Street, Worcester. The new quarters will also serve as a home for the society and accommodate the society's blood bank (THE JOURNAL, September 26, p. 299).

Activities at Harvard—Dr. Joseph S. Lichty Shaker Heights, Ohio, of the Cleveland Trust Company has been appointed assistant dean of the faculty of medicine at Harvard University and assistant professor of medical administration. Dr. Franklin F. Snyder, Chicago, has been appointed associate professor of anatomy and obstetrics at the medical school. Frederick J. Stare, Ph.D. Madison, Wis., has been appointed assistant professor of nutrition, which is reported to be a new title connecting the clinical and laboratory branches of nutritional science. Dr. Stare will work both in the laboratory and in the field in connection with the medical school and the school of public health. Henry P. Fraffers, Ph.D., an immunochemist, has been named to a new title at Harvard, that of assistant professor of comparative pathology and biologic chemistry. A new office, known as "Medical School Research Laboratories" has been organized in the medical school under Mr. U. Haskell Crocker. The object is to coordinate and centralize the business details of the various research projects in progress in the medical school, operating under contract with the office of scientific research and development.

MISSISSIPPI

Changes in Health Personnel—Dr. William D. May, Meridian, has been named director of the Alcorn County Health Department, succeeding Dr. Robert H. DeJarnette, Corinth, who has entered the army.—Dr. John H. Hines, Canton, has resigned as health officer of Madison County to join the army.—Dr. James F. Bradley, Liberty, has been appointed health officer of Noxubee County, succeeding Dr. George E. Gibbons, Macon.—Dr. Margaret M. Scannell, formerly of Meridian, has been named medical director of the Sunflower County Department of Health, succeeding Dr. Andrew Hedmieg, Indianola, who has entered the military service.—Dr. Thomas Burk, Rayville, La., has been appointed health officer of Copiah County with offices in Hazlehurst, succeeding Dr. John C. McGuire, Hazlehurst.

MISSOURI

New Professor of Psychiatry—Dr. Edwin F. Gildea, formerly associate professor of psychiatry at Yale University School of Medicine, New Haven, Conn., is now professor of psychiatry and administrative head of the department of neuropsychiatry at Washington University School of Medicine, St. Louis. Dr. Gildea graduated at Harvard Medical School, Boston, in 1924.

First Terry Lecture—The first annual Robert J. Terry Lecture will be delivered before the St. Louis Medical Society December 1, by Dr. Stuart Mudd, Philadelphia, on "Morphology of Pathogenic Bacteria and Viruses as Shown by the Electron Microscope, with Some Practical Implications." The lecture was established through a bequest in the will of the late Dr. William T. Coughlin, a former member of the society. The will stipulated that the income from a bequest of \$5,000 be used to establish and maintain a lecture or lectures to be given annually at the Medical Society Building and to be known as the "Robert James Terry Lecture (or Lectures)." Dr. Coughlin stated in his will "This I do as a testimonial of my gratitude to Dr. Terry, who gave me a position as assistant in his laboratory, which afforded me not only an opportunity to learn the anatomy of the human body and thus to fit myself for surgery but also the means whereby I was enabled to begin my practice in St. Louis." Dr. Coughlin died on May 22, 1940. Dr. Terry is professor emeritus of anatomy at Washington University School of Medicine.

NEW JERSEY

Explosion of Anesthetic Kills Patient—According to the New York Times an explosion of an anesthetic killed a patient, November 10, as he was receiving a blood transfusion after a chest operation at the New Jersey Sanatorium for Tuberculous Diseases at Glen Gardner. Internal hemorrhage caused the death of the 25-year-old patient fifty minutes after the explosion. Physicians and others working in the operating room were not injured. William J. Ellis, Ph.D., Trenton, state commissioner of institutions and agencies, said a static spark was the only plausible explanation of the explosion, and the mishap was "beyond human power to anticipate." The room was adequately protected against a spark from any of the electrical apparatus. It was explained that the explosion occurred as the mask hose was being removed from the machine which mixed cyclopropane gas with oxygen. There was no negligence on the part of any one, it was stated. It was further reported that the patient was in an advanced stage of tuberculosis and the chest operation was decided on as the only means of saving his life.

NEW YORK

Mr. Armstrong Dies—Charles Ralph Armstrong, for thirty years superintendent of the Trudeau Sanatorium, Trudeau, died, November 9, aged 71.

Society News—The Onondaga County Medical Society and the Syracuse Academy of Medicine were addressed, November 10, by Drs. Percival K. Menzies on "Traumatic Rupture of the Liver" and Robert K. Brewer, "Review of Liver Function Tests."—Dr. Walter Brandon Macomber, Albany, discussed "Principles of Plastic Surgery and Their Application" before the Medical Society of the County of Albany, November 25.

New York City

New Women's Field Army Headquarters—The board of managers of the Memorial Hospital for the Treatment of Cancer and Allied Diseases has given the Women's Field Army of the New York City Cancer Committee space in its old building at Central Park West and 106th Street for new headquarters and the workroom of the surgical dressings committee. Space has also been given in the same building for a permanent exhibit of the cancer educational material of the city cancer committee.

Portrait of Dr. Walter Niles—A portrait of the late Dr. Walter L. Niles was presented to Cornell University Medical College, November 13. Joseph C. Hinsey, Ph.D., dean, presided at the presentation ceremonies. Dr. Malcolm Goodridge, president of the New York Academy of Medicine, gave the memorial address. Dr. Connie M. Guion, chairman of the portrait committee, made the presentation and Edmund E. Day, LL.D., president of the school, gave the speech of acceptance. Dr. Niles graduated at Cornell in 1902. He was professor of clinical medicine from 1916 until his death in 1941 and had been dean from 1919 to 1928. He was acting dean of the school at the time of his death.

Refresher Course in Cardiovascular Diseases—The New York Academy of Medicine and the New York Heart Association are cooperating in a series of lectures on cardiovascular diseases. The first in the series was delivered on November 25 by Dr. Robert L. Levy on "Management of the Patient Who Has Recovered from Acute Coronary Occlusion." Others in the series will be:

Dr. William Goldring, December 23, "The Management of Hypertension"; Dr. Edwin P. Maynard Jr., Brooklyn, January 27, "The Management of Cardiovascular Syphilis"; Dr. Harry Gold, February 24, "The Management of Heart Failure"; Dr. Irving S. Wright, March 24, "The Management of Peripheral Vascular Disease"; Dr. Currier McEwen, April 28, "The Management of Rheumatic Fever"; Dr. Arthur C. De Graff, May 26, "The Management of Cardiac Arrhythmias".

Agencies Merge to Care for Orphans—The Home for Hebrew Infants and the New York Association for Jewish Children, child care agency of the Federation for the Support of Jewish Philanthropic Societies of New York City, have been merged, completing the integration into one body of all federation agencies devoted to the care of orphaned and dependent children, including institutional care, foster home care and after-care for graduates of institutions and foster homes. The merged group will bear the name of the New York Association for Jewish Children and under the consolidation becomes the largest single child care agency in the country, according to the New York Times. Infants now in the home at 100 West Kingsbridge Road are being placed in foster homes under the supervision of the association and the building will serve as administrative center for the boarding out of children.
